11

12 5 Emergency departments are challenging research settings truly informed consent can
13 6 be difficult to obtain. A deeper understanding of emergency medical patients' opinions
14 7 about research is needed. We conducted a systematic review and meta-summary of
15 8 quantitative and qualitative studies on which values, attitudes, or beliefs of emergent
16 9 medical research participants influence research participation. We included studies of
17 10 adults that investigated opinions toward emergency medicine research participation.
18 11 We excluded studies focused on the association between demographics or consent
19 12 document features and participation and those focused on non-emergency research. In
20 13 August 2011, we searched the following databases: MEDLINE, EMBASE, Google
21 14 Scholar, Scirus, PsycINFO, AgeLine, and Global Health. Titles, abstracts, and then full
22 15 manuscripts were independently evaluated by 2 reviewers. Disagreements were
23 16 resolved by consensus and adjudicated by a third author. Studies were evaluated for
24 17 bias using standardized scores. We report themes associated with participation or
25 18 refusal. Our initial search produced over 1800 articles. A total of 44 articles were
26 19 extracted for full-manuscript analysis and 14 were retained based on our eligibility
27 20 criteria. Among factors favoring participation, altruism and personal health benefit had
28 21 the highest frequency. Mistrust of researchers, feeling like a "guinea pig", and risk were
29 22 leading factors favoring refusal. Many studies noted limitations of informed consent
30 23 processes in emergent conditions. We conclude that highlighting the benefits to the

32 INTRODUCTION

33 Emergency departments are an increasingly important setting for conducting medical
34 research(1). In the United States alone, there were approximately 123.8 million visits to
35 emergency departments in 2008.(2) Emergency departments care for populations that
36 are traditionally under-represented in medical research, such as minorities and those
37 without other sources of medical care.(2) Interventions in a variety of time-sensitive
38 diseases can reduce morbidity and mortality.(3, 4) However, in patients with emergent
39 conditions, the effects of acute illness, time constraints, lack of access to family or
40 physicians, and other challenges complicate the informed consent process.(5-7)
41 In order to rationally propose solutions to the difficulties in enrolling patients in
42 emergency medical trials, it is necessary to synthesize a deeper understanding of the
43 motivations and concerns of potential emergency medicine research participants. Such
44 an understanding will allow us to make the process more patient-centered.(8) Prior
45 work has primarily focused on attitudes toward research in patients with non-emergent
46 conditions.(9, 10) Factors found to be associated with research participation in non-
47 emergent conditions include, among others: demographics, patients' health beliefs, and
48 disease severity.(11, 12) Prior work in emergency settings has examined the
49 relationship between patient demographics or aspects of informed consent documents
50 and research participation.(13-15) These studies have not been able to lead to
51 implementable proposals for improving the informed consent process in emergency
52 medicine research.
53 Some prior qualitative and survey studies have examined patients with specific
54 emergency medical conditions and their attitudes toward research. We seek to collate

1
2
3 55 and synthesize the available literature to understand emergency medical patients'
4
5
6 56 perspective without regard to specific medical conditions. This is due to the fact that
7
8 57 there is some non-specificity of the symptoms of many emergent medical conditions(16)
9
10 58 and many emergency medicine trials require enrollment based on symptoms, not
11
12 59 diagnoses. The objective of this study, then, was to conduct a systematic review and
13
14 60 meta-summary to evaluate what values, attitudes, or beliefs on the part of potential or
15
16 61 actual research participants with emergent medical conditions influence participation in
17
18 62 research.
19
20
21
22
23

24 63 **METHODS**

27 64 **Study design**

30 65 This systematic review is reported in accordance with the Preferred Reporting Items for
31
32 66 Systematic Review and Meta-Analyses (PRISMA) statement.(17)
33
34
35

36 67 **Eligibility criteria**

38 68 We considered studies with the following criteria: studies including patients over 18
39
40 69 years of age, and any study reporting on or investigating the values, attitudes, or beliefs
41
42 70 toward emergency medical research (studies conducted in the emergency department
43
44 71 or on emergency medical conditions) from participants' point of view. In addition, the
45
46 72 following exclusion criteria were used: any study reporting the association of participant
47
48 73 demographics (age, race/ethnicity, gender, economic, or education status) with
49
50 74 research participation, any study primarily reporting the association of features of the
51
52 75 consent process with research participation, and any study reporting on attitudes toward
53
54 76 non-emergency research. We eliminated studies focused on demographics as they
55
56
57
58
59
60

1
2
3 77 were beyond the scope of the intended paper and we did not plan any subgroup
4
5 78 analyses a priori.
6
7

8 9 79 **Information sources**

10
11 80 In August 2011, we searched the following electronic databases: MEDLINE (accessed
12
13 81 by PubMed), EMBASE, Google Scholar, Scirus, PsycINFO (via EBSCO), AgeLine (by
14
15 82 AARP) and Global Health. We did not use limits for date and language when
16
17 83 conducting the search. In addition, we searched the references of the included articles
18
19 84 manually. We also performed a citation analysis of the included studies using Google
20
21 85 Scholar, and sought experts' suggestions.
22
23
24
25
26

27 86 **Search**

28
29
30 87 The initial search comprised the MeSH terms "Emergencies", "Patients", "Research",
31
32 88 "Perception", "Values", "Culture", and related entry terms. The complete search strategy
33
34 89 used for the PubMed database is shown in Appendix 1 (available online).
35
36
37

38 90 **Study selection**

39
40
41 91 Titles and abstracts of the retrieved articles were independently evaluated by 2
42
43 92 reviewers (A.P. and T.M.). Both reviewers have prior experience in performing
44
45 93 systematic searches and reviews. Abstracts that did not provide enough information
46
47 94 regarding the eligibility criteria were kept for full-text evaluation. Two reviewers (T.M.
48
49 95 and L.L.H.O.) independently evaluated full-text articles and determined study eligibility.
50
51 96 Disagreements were solved by consensus and if disagreement persisted, they sought
52
53 97 the lead author's opinion (A.L.).
54
55
56
57
58
59
60

1
2
3 98 **Risk of bias across studies**
4

5
6 99 Risk of bias was evaluated by reviewers ranking each study according to items adapted
7
8 100 from Bennett, et al.(18) for surveys and the online Joanna Briggs Institute-Qualitative
9
10 101 Assessment and Review Instrument (JBI-QARI, (The Joanna Briggs Institute, University
11
12 102 of Adelaide, Australia)) for qualitative studies.
13
14

15
16
17 103 **Data extraction**
18

19 104 Two reviewers (T.M. and L.L.H.O.) independently conducted initial data extraction. The
20
21 105 lead author (A.L.) reviewed all final studies and iteratively generated the list of themes.
22
23 106 Characteristics of the studies collected included year of publication, authors, geographic
24
25 107 region of first author, objective, study design, setting, intervention studied (if any),
26
27 108 participant sampling methods, inclusion and exclusion criteria, data collection and
28
29 109 analysis methods, participants' characteristics, main results, and authors' conclusion(s).
30
31
32
33

34
35 110 **Primary data analysis**
36

37 111 Qualitative meta-summary(19) is a quantitatively oriented aggregation approach to
38
39 112 research synthesis of both qualitative and survey studies. As opposed to traditional
40
41 113 meta-analysis in which bivariate or multivariable research findings are combined,
42
43 114 qualitative meta-summary uses descriptive findings from primarily quantitative and
44
45 115 qualitative studies. The primary requirements for inclusion are that the findings are
46
47 116 descriptive and can be seen as addressing the same question (in this case, "What
48
49 117 factors are associated with participation in emergency medicine research?").
50
51
52 118 From the reports of qualitative research findings, we extracted themes or patterned
53
54 119 responses from the results sections of the collected studies regardless of how many
55
56
57
58
59
60

1
2
3 120 participants endorsed the themes. When possible, we extracted sample quotations from
4
5
6 121 participants. From the quantitative reports, we extracted descriptive information on the
7
8 122 factors associated with participation, which were presented in survey format (i.e.,
9
10 123 proportion of participants reporting each factor). The lead author created a draft list of
11
12 124 themes based on unstructured summaries of findings from each study created by the 2
13
14 125 independent article extractors. This framework was then iteratively refined through
15
16 126 subsequent reviews of the results sections of final articles. These interim versions were
17
18 127 reviewed by the lead author with one author who has experience with qualitative meta-
19
20 128 summary and adjustments made accordingly. The final version was reviewed by a
21
22 129 panel of 3 content experts for consensus: the aforementioned expert on qualitative
23
24 130 meta-summary, one with expertise in bioethics, and a third with an expertise in clinical
25
26 131 trials processes. The themes were grouped by similarity, and within each group, brief
27
28 132 descriptions of the findings were generated.(19-21) We did not assume that the
29
30 133 presence of a factor that favored participation implied that the absence of that factor
31
32 134 favored refusal, unless specifically cited. For example, although previous experience
33
34 135 with research favored participation, the lack of previous experience was not assumed as
35
36 136 a reason for refusal.

37
38
39 137 To represent the magnitude of each finding, “frequency effect sizes” were generated by
40
41 138 dividing the number of studies citing a particular theme by the total number of studies in
42
43 139 our final list (14 studies). To represent the magnitude of each report, “intensity effect
44
45 140 sizes” were calculated 2 ways. Specifically, for each study, the number of findings with a
46
47 141 frequency effect size >25% was divided by the total number of findings with frequency
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 142 effect size >25%(16 themes). Additionally, for each study, the number of themes it cited
4
5
6 143 was divided by the total number of themes overall (43 themes).
7
8
9

10 144 **RESULTS**

11 12 13 145 **Study selection**

14
15 146 Our initial search produced over 1800 articles from among the various databases. Of
16
17
18 147 these, on the basis of title and abstract analysis, a total of 44 articles were extracted for
19
20 148 full-manuscript analysis of appropriateness. Analysis of the references and citations of
21
22 149 these articles produced an additional 9 articles for review. From among these 53
23
24
25 150 articles, 14 were retained based on our eligibility criteria (Figure 1. Study Workflow).
26
27
28
29

30 152 **Study characteristics**

31
32 153 Of the 14 articles that met eligibility criteria, 6 were qualitative studies, 8 included survey
33
34 154 items, and 3 contained elements of both qualitative or open-ended questions and
35
36 155 quantitative survey items (Table 1). Five studies examined suspected myocardial
37
38
39 156 infarction patients, 3 focused on stroke patients, 1 focused on sudden cardiac near-
40
41 157 death survivors, and the rest examined undifferentiated emergency department
42
43
44 158 patients. The number of patients involved per study ranged from 11 to 40 in the
45
46 159 qualitative studies and 103 to 1,901 in the quantitative survey studies. Although we did
47
48
49 160 not set a language filter, our search produced publications exclusively in the English
50
51 161 language and primarily in American and Western European research contexts.
52

163 * The data inserted on the "Age" column is the mean age of all participants in the study. However, some studies did not provide this
 164 information, and, for these studies, we inserted in this column the available non-standardized data.

165 † Non-standardized data, as explained above.

166

167 Risk of bias across studies

1
2
3 168 No studies were excluded on the basis of bias. Overall survey studies were of
4
5 169 moderate quality. Almost all of the survey studies included a justification of the
6
7
8 170 research question, instrument pre-testing, and description of sample; none provided
9
10 171 clear evidence of reliability, validity or sample size calculation (Appendix 2, available
11
12 172 online). Quality was high among the primarily qualitative studies. Nearly all
13
14
15 173 demonstrated congruity between the research method and the question, data collection
16
17 174 methods, representation and interpretation of the data. None, however, addressed the
18
19 175 influence of the researcher on the research or vice versa (Appendix 3, available online).
20
21
22 176

23 24 177 **Themes**

25
26
27 178 The retained reports presented a number of themes influencing participant participation
28
29 179 in research (Table 2 and Appendix 4). Among themes favoring participation, a sense of
30
31 180 altruism and personal health benefit had the highest frequency effect sizes. Among the
32
33 181 personal health benefits noted were access to better treatments, and access to more
34
35 182 skilled care providers, follow up care, or other resources. Other common themes
36
37 183 favoring participation included having a good understanding of the risks and benefits of
38
39 184 the study, trust in their physician, and an awareness by the participant that there are no
40
41 185 other effective treatments for their condition.
42
43
44

45
46 186 **Table 2: Themes favoring participation.**

26	Effects of acute illness		
27			
28	Did not want to delay treatment	6 (43%)	Ågård A (2001)(22); Gammelgaard A (2004)(25);
29			Gammelgaard A (2004)(32) (15); Kasner SE (2010)(26);
30			Mangset M (2008)(23); Williams BF (2003)(28) (22%)
31			
32	Too little time- made a rushed decision	4 (29%)	Ågård A (2001)(22); Mangset M (2008)(23); Gammelgaard
33			A (2004)(32) (40%); Mangset M (2008)(23)
34			
35	Too sick/too much pain: "willing to sign	4 (29%)	Ågård A (2001)(22); Gammelgaard A (2004)(25); Mangset
36	anything"		M (2008)(23); Williams BF (2003)(28)
37			
38	Effect of pain meds/sedatives: "not in my	2 (14%)	Ågård A (2001)(22); Gammelgaard A (2004)(25)
39	right mind"		
40			
41			
42			
43	187		*Survey studies only.
44			
45	188		
46			
47	189		Mistrust of researchers and fear of the actual risk of the research were two of the
48			
49	190		leading themes favoring refusal of participation. Coupled with mistrust of researchers
50			
51	191		was the specific use of the term "guinea pig". Use of a placebo arm and of
52			
53	192		randomization were also cited as deterrents from participation.
54			
55

59			
60			

1
2
3 193 A number of the studies focused on participants' ability to comprehend the complexities
4
5
6 194 of research. Some participants were not even aware that they were participating in (or
7
8 195 had been asked to participate in) research. Others did not understand their ability to
9
10 196 refuse participation. Many misunderstandings were attributed to limitations of informed
11
12 197 consent processes in patients with emergent conditions (Table 3 and Appendix 5).
13
14 198 Additionally, the format of information presentation (oral versus written) influenced some
15
16 199 respondents' likelihood of participating. Many themes related to informed consent were
17
18 200 associated with either participation or refusal depending on the respondent.
19
20
21

22 **Table 3: Themes favoring refusal.**
23

Themes	No. of Studies (%)	Studies (% of study participants endorsing *)
Not enough financial compensation	1 (7%)	Biros MH (2009)(29) (12%)
Too much of a time investment	2 (14%)	Biros MH (2009)(29) (53%); Wilets I (2003)(34) (6%)
Inconvenience	2 (14%)	Paradis C (2010); Biros MH (2009)(29) (25%)
Feeling like a "guinea pig"	8 (57%)	Ågård A (2001)(22); Blixen CE (2005)(24); Dickert NW (2009)(27); Gammelgaard A (2004)(25); Mangset M (2008)(23); Paradis C (2010)(33); Wilets I (2003)(34) (49%); Williams BF (2003)(28) (6%)
Drug companies involvement	3 (21%)	Dickert NW (2009)(27); Kasner SE (2010)(26); Wilets I (2003)(34) (74%)
Privacy	2 (14%)	Biros MH (2009)(29) (20%); Wilets I (2003)(34) (5%)
Government involvement	1 (7%)	Wilets I (2003)(34) (74%)
Risk was too great	6 (43%)	Biros MH (2009)(29) (23%); Dickert NW (2009)(27); Gammelgaard A (2004)(32) (37%); Mangset M (2008)(23); Wilets I (2003)(34) (38%); Williams BF (2003)(28) (6%)
Prefer non-experimental/control treatment	4 (29%)	Gammelgaard A (2004)(25); Mangset M (2008)(23); Gammelgaard A (2004)(32) (3%); Yuval R (2000)(35) (49%)
Didn't like possibility of receiving a placebo	3 (21%)	Kasner SE (2010)(26); Mangset M (2008)(23); Yuval R (2000)(35) (28%)

Didn't like the idea of randomization	4 (29%)	Ågård A (2001)(22); Dickert NW (2009)(27); Gammelgaard A (2004)(32) (18%); Kasner SE (2010)(26)
Not interested in research	1 (7%)	Wilets I (2003)(34) (24%)
Too much or too complex information	2 (14%)	Gammelgaard A (2004)(25); Paradis C (2010)(33)
Not enough information	3 (21%)	Biros MH (2009)(29) (21%); Paradis C (2010)(33) (29%); Gammelgaard A (2004)(32) (7%)
Written IC presentation	2 (14%)	Ågård A (2001)(22); Gammelgaard A (2004)(25)
Did not want to delay treatment	2 (14%)	Gammelgaard A (2004)(25); Gammelgaard A (2004)(32) (31%)
Too little time/felt rushed	2 (14%)	Biros MH (2009)(29) (53%); Paradis C (2010)(33) (29%)
Felt too sick	2 (14%)	Gammelgaard A (2004)(25); Paradis C (2010)(33)

202 *Survey studies only.

203

204 There was a trend toward qualitative studies having higher intensity effect scores, with
 205 several studies contributing to more than half of the themes with frequency effect sizes
 206 greater than 25% (Table 4 Intensity Score A, Columns A & B).

207 **Table 4. Intensity Effect Sizes**

Reference	No of Themes with Frequency Effect Size >25%	Intensity Score A (column A/total themes with Frequency Effect Size >25% (16))	Total No of Themes	Intensity Score B (column C/ Total themes(43))
Ågård A (2001)(22)	11	69%	15	35%
Biros MH (2009)(29)	3	19%	12	28%
Blixen CE (2005)(24)	6	38%	8	19%
Dickert NW (2009)(27)	10	63%	13	30%
Gammelgaard A (2004)(32)	10	63%	18	42%
Gammelgaard A (2004)(25)	11	69%	15	35%

Kasner SE (2010)(26)	8	50%	12	28%
Mangset M (2008)(23)	11	69%	12	28%
McClure KB (2002)(31)	2	13%	3	7%
Paradis C (2010)(33)	6	38%	15	35%
Triner W (2007)(30)	1	6%	1	2%
Wilets I (2003)(34)	8	50%	15	35%
Williams BF (2003)(28)	8	50%	9	21%
Yuval R (2000)(35)	6	38%	8	19%

208

209 However, there was considerable overlap between the themes contributed by qualitative
 210 versus quantitative survey studies. No single study contributed the majority of the
 211 overall findings, with all studies producing less than 50% of the total available themes
 212 (Table 4, Intensity Score B, Column C and D).

213 DISCUSSION

214 Understanding emergency patients' views of research will allow us to accommodate
 215 their unique needs. Several qualitative and quantitative survey studies have been
 216 conducted to examine participants' reasons for participating in emergency medical
 217 research. To our knowledge, these studies have not been synthesized across
 218 disciplines in a manner that informs researchers of emergent conditions. Use of
 219 qualitative meta-summary allows extraction of themes from both quantitative survey and
 220 qualitative work, recognizing that the differences between the two approaches are not
 221 as substantial as many suppose. This leverages the strengths of qualitative work
 222 (depth and greater possibility for unanticipated responses) with those of quantitative

1
2
3 223 survey studies (standardization of assessment, sample size sufficient for inferential
4
5
6 224 testing). Another unique strength of our meta-summary was the identification of themes
7
8 225 that both favored and disfavored participation dependent on the respondent. Such bi-
9
10 226 directional findings may have been otherwise difficult to elucidate in individual
11
12 227 qualitative studies or meta-analyses. Our analysis of intensity scores indicates that
13
14
15 228 qualitative studies tended to have a high number of factors that were reported in several
16
17 229 other studies and that no study contributed more than 50% of the total themes
18
19
20 230 generated.

21
22 231
23
24 232 Among the most commonly reported motivators was personal health benefit and
25
26
27 233 altruism, whereas the most commonly cited barriers were lack of trust and concern over
28
29 234 risk. Some themes, such as time constraints, were reported to favor either participation
30
31 235 or refusal, depending on the respondent. We also noted inadequacies of the informed
32
33 236 consent process in emergency research. Several studies documented participant
34
35
36 237 participation despite poor understanding of basic principles such as voluntariness,
37
38 238 consent, randomization, or the risks and benefits of research.

39
40
41 239

42 43 240 **Personal health benefit**

44
45
46 241 Adam Smith posited in 1759 the “invisible hand” of self-interest as a driver of
47
48 242 decisions.(36) Accordingly, it is not surprising that participants will participate in
49
50 243 research that they feel is likely to benefit them. Self-interest was also noted in the
51
52 244 influence of non-health benefits such as financial compensation, convenience, and
53
54
55 245 access to specialists. This is consistent with prior research on this topic in other
56
57
58
59
60

1
2
3 246 fields.(37) In many cases, this belief in self-interest is held so strongly that it even
4
5
6 247 overpowers directly conflicting information provided during informed consent.
7
8 248 “Therapeutic Misconception” is the term used for the notion that participating in research
9
10 249 is a means of providing the best care available as opposed to an attempt to further
11
12 250 scientific knowledge. This phenomenon was present even in those with firm
13
14
15 251 understanding of trial mechanics, as witnessed by the statement of one participant:
16
17 252 “So, I reckoned that all things being equal it would be better to go to
18
19 253 the angioplasty centre, I mean getting the chance to go; I’m aware of
20
21
22 254 the drawing of lots and the existence of a control group and that.”(25)
23
24 255 Another example occurred in the Paradis, et al.(33), study in which participants reported
25
26 256 personal health benefit in a study for which they were explicitly informed that they would
27
28 257 receive no direct benefit. Thus, highlighting the benefits of the study to the participant is
29
30 258 likely to improve enrollment, but must be done in a measured fashion to avoid
31
32 259 therapeutic misconception.
33
34
35
36
37
38

39 261 **Altruism**

40
41 262 Altruism has been found to be an important factor to research participation. This would
42
43 263 appear to be somewhat inconsistent with the notion of personal health benefit until it is
44
45 264 realized that altruism was expressed in many different ways, consistent with the
46
47 265 academic literature on this topic.(38) While some participants expressed altruism in
48
49 266 furthering scientific knowledge and helping others, another way it was expressed was a
50
51 267 hope to improve future medical care. This implicitly would include future benefit for the
52
53 268 participant as well. For some, the sense of altruism was tied to their sense of belonging
54
55
56
57
58
59
60

1
2
3 269 to a particular group that would benefit from the research, such as gender, race,
4
5
6 270 nationality, or health condition. Still others might posit that merely appearing altruistic is
7
8 271 a form of benefit. Thus, it would seem that highlighting a study's ability to help others
9
10 272 would increase participation.
11

12
13 273

14 15 274 **Mistrust**

16
17 275 Previous studies have noted mistrust in medical researchers as a barrier to research
18
19
20 276 participation. This finding has been noted in numerous settings of research and across
21
22 277 cultures.(39, 40) Many associate a sense of mistrust to past research misconduct.(41)
23
24 278 The connection between improper conduct of research and mistrust is also expressed
25
26
27 279 by multiple participants' use of the specific term "guinea pig". The use of guinea pigs for
28
29 280 medical research dates to the 17th century(42) and the term has a negative connotation
30
31 281 of research experimentation in popular culture. In the studies we reviewed, participants
32
33 282 universally used the term to describe their mistrust of medical research, indicating that
34
35 283 they felt they would be placed in danger in order to further scientific knowledge. Others
36
37 284 expressed concern over the protection of their privacy and over relationships between
38
39 285 researchers and sponsors. Increasing public trust in research has been a longstanding
40
41 286 national priority, however, it is not clear whether there are simple methods for doing so.
42
43
44

45 287

46 47 48 288 **Risk**

49
50 289 It is not surprising that patients with emergency conditions are sensitive to the risk
51
52 290 involved in research. In an outpatient setting, participants who had a negative reaction
53
54
55 291 to the informed consent language regarding risks were less likely to enroll into a
56
57
58
59
60

1
2
3 292 hypothetical trial.(43) Further evidence of this sensitivity is revealed in the studies by
4
5
6 293 Dickert, et al.,(27) and McClure, et al.,(31) in which acceptance of studies is higher for
7
8 294 diagnostic trials as opposed to interventional trials. As noted in the study by Blixen, et
9
10 295 al.,(24) emergency medicine patients are particularly sensitive to any intervention that
11
12 296 could result in death, even if the likelihood is remote. An important exception was noted
13
14
15 297 among patients with known poor prognosis. While all studies attempt to mitigate risk,
16
17 298 the manner in which this risk is communicated to patients may be more important than
18
19 299 the actual level of risk. Risk communication remains a difficult challenge for
20
21
22 300 researchers.(44) This aligns with prior research demonstrating poor comprehension
23
24 301 and a lack of acceptance of common research concepts among lay people.(45)
25
26

27 302

29 303 **Informed consent processes**

30
31 304 The inherent difficulties in performing informed consent in patients with time-sensitive
32
33 305 conditions were also made apparent. In a number of cases, limitations in time, inability
34
35 306 to comprehend complex information, and the emotional aspects of acute illness resulted
36
37 307 in either uninformed refusal or misguided participation in research. In some instances,
38
39 308 a particular factor (e.g.s lack of time, pain) led to either increased likelihood of
40
41
42 309 participation (albeit misguided) or decreased likelihood, depending on the patient.
43
44
45 310 Other standard research methods such as randomization and use of placebo were also
46
47 311 cited as deterrents to participation. This may be due to poor comprehension of such
48
49 312 procedures and their rationale. The fact that some participants did not even understand
50
51 313 that they were participating in research is alarming. This reinforces the fiduciary
52
53
54 314 responsibility of the researcher in the emergency setting. Although these qualities are
55
56
57
58
59
60

1
2
3 315 not unique to emergency care research,(46-48) they do point to the need for improved
4
5
6 316 methods of providing information to potential research participants. The preference of
7
8 317 respondents for oral versus written information suggests that existing informed consent
9
10 318 documents are a suboptimal means of communication. Additionally, assessment of
11
12 319 patients' comprehension of information is poorly done (and poorly documented) in our
13
14
15 320 current paradigm of informed consent.

16
17 321 The factors noted above point to several potential solutions to ensuring safe, ethical
18
19
20 322 enrollment of patients with emergency medical conditions. Just as we must strive to
21
22 323 improve the ways we provide medical care, so too must we strive to improve our
23
24 324 research methods, including informed consent. The consensus of the research
25
26
27 325 community is that informed consent documents are too long.(49) However, as noted
28
29 326 above, patients do not view the documents as the optimal means of communication,
30
31 327 suggesting the need for other methods. Innovative interventions might outperform
32
33
34 328 traditional informed consent processes; for example, multimedia presentation or simple
35
36 329 test-retest methods(50) have not been explored in emergency medicine research
37
38
39 330 contexts. Given that that the critical factor in the consent process may be the human
40
41 331 interaction between researcher and patient (50), technological advances will only aid
42
43 332 the consent process if they can retain this factor.

44
45 333 Second, a public health education program highlighting research participants' rights and
46
47
48 334 protections might be beneficial. This program could educate the public about the
49
50 335 existing patient safeguards required for any research study, including the voluntariness
51
52 336 of research participation. This would potentially reduce the amount of new information
53
54
55 337 that potential research participants would face in the setting of acute illness.
56
57
58
59
60

338 Additionally, research study designs might be able to mitigate the effect of acute illness
339 by waiting until stabilizing treatments are started before approaching participants.

340 **Limitations**

341 The present study is limited by its reliance on published literature. As such, it is
342 constrained by bias by authors in interpreting data and publication bias. In particular, it
343 is possible that preconceived notions of authors about factors influencing research
344 participation are highlighted more frequently. Unlike quantitative meta-analysis, we
345 cannot perform a forest plot to gain insight into any publication bias. We did perform a
346 quality analysis, with evidence of high quality studies. A number of our studies focused
347 on patients with cardiac and neurologic disease, potentially limiting their generalizability.
348 However, we also extracted several articles performed on a general emergency
349 department population.

350 We may have missed or inappropriately excluded some relevant studies. However, we
351 used rigorous, standardized methods for identifying articles. Finally, we report in our
352 basic quantitative analysis the number of studies citing a theme. The quantity of articles
353 reporting a factor may not reflect its relative importance to respondents. Additionally,
354 given the wide range in the number of respondents in any given study, an increasing
355 number of studies citing a theme does not necessarily reflect more respondents.

356 **CONCLUSIONS**

357 Understanding emergently ill patients' views of research will allow us to adapt research
358 processes to accommodate patients' needs. It will also guide Institutional Review
359 Boards on how to conduct activities to prevent exploitation of emergently ill patients. In

1
2
3 360 this systematic review and meta-summary, we found several factors associated with
4
5
6 361 research participation. New methods for conducting informed consent are needed to
7
8 362 overcome inherent obstacles to information transmission in emergency settings. The
9
10 363 relative importance of these factors should be prospectively tested in experimental
11
12
13 364 fashion.
