COMPLEXITY OF RANDOMIZED ALGORITHMS FOR UNDERDAMPED LANGEVIN DYNAMICS *

YU CAO†, JIANFENG LU‡, AND LIHAN WANG§

Abstract. We establish an information complexity lower bound of randomized algorithms for simulating underdamped Langevin dynamics. More specifically, we prove that the worst $L^2$ strong error is of order $\Omega(\sqrt{dN^{-3/2}})$, for solving a family of $d$-dimensional underdamped Langevin dynamics, by any randomized algorithm with only $N$ queries to $\nabla U$, the driving Brownian motion and its weighted integration, respectively. The lower bound we establish matches the upper bound for the randomized midpoint method recently proposed by Shen and Lee [NIPS 2019], in terms of both parameters $N$ and $d$.

Key words. Underdamped Langevin dynamics, randomized algorithms, information-based complexity, order optimal, randomized midpoint method

AMS subject classifications. 65C20, 65C50

1. Introduction. The underdamped Langevin dynamics have been widely used to sample high-dimensional probability distributions [57, 35, 43], as it could provide a faster convergence rate compared to the overdamped Langevin dynamics. The analysis of the sampling algorithms based on underdamped Langevin dynamics consists of two key aspects:

(i) the mixing time of continuous-time underdamped Langevin dynamics;
(ii) the time-discretization error for numerically integrating underdamped Langevin dynamics.

The first question has been widely studied for various metrics of convergence, see, e.g., [43, 9, 7, 49, 3].

Our focus in this work is the performance of discretization algorithms for underdamped Langevin dynamics. This has also been quite extensively studied, in terms of both asymptotic analysis [42, 34, 55, 13] and non-asymptotic analysis [4, 5, 7, 32, 50].

The algorithm with the best rate up to date was proposed by Shen and Lee [50]. Their randomized midpoint method for underdamped Langevin dynamics has a strong $L^2$ error $O(\sqrt{dN^{-3/2}})$ using only $N$ gradient queries, where $d$ is the dimension. On the other hand, it is not clear yet from the literature what error rate an optimal algorithm can achieve. In other words, what the intrinsic difficulty of numerical integration of underdamped Langevin dynamics is. This paper provides an answer in the framework of information-based complexity (IBC). In particular, we show that the randomized midpoint method is order optimal with respect to both $d$ and $N$.

Information-based complexity [41, 53], which is closely related to the notion of the information-theoretic lower bound, studies the intrinsic complexity of a family of computational problems, based on the type of queries that one has, rather than focusing on a particular algorithm for the task. Intuitively, the algorithmic performance

would depend on the information one could acquire (for example, the gradients of the potential function $U$ for Langevin dynamics). IBC aims to establish a lower bound of the accuracy of a family of algorithms, provided the amount and type of information.

In this work, we adopt the framework of IBC to study randomized algorithms for approximating the strong solution of the underdamped Langevin dynamics with gradient queries to strongly convex potentials and also the driving Brownian motion.

1.1. Underdamped Langevin dynamics. We consider the following underdamped Langevin dynamics $(X_t, V_t) \in \mathbb{R}^d \times \mathbb{R}^d$ (we adopt the parameter scaling used in [5, 50], which is slightly different from the usual physical model of underdamped Langevin dynamics)

\[
\begin{align*}
    dX_t &= V_t \, dt, \\
    dV_t &= -2V_t \, dt - \frac{1}{L} \nabla U(X_t) \, dt + \frac{2}{\sqrt{L}} \, dW_t,
\end{align*}
\]

(1.1)
on the time interval $[0, T]$, with the fixed initial condition $X_0 = x^*$ and $V_0 = 0$, where $x^* \in \mathbb{R}^d$ is a local minimum of the potential function $U$. The parameter $L > 0$ has a physical meaning as the mass of the particle. The unique stationary distribution of (1.1) is $\rho_\infty(x, v) \propto \exp\left(-\frac{U(x) + |v|^2}{2L}\right)$. As time $t \to \infty$, the distribution of $(X_t, V_t)$ converges to the equilibrium exponentially fast under mild conditions; see, e.g., [33, 54, 43, 9, 49, 10, 3]. Generalization of our main result (Theorem 1.2) below to underdamped Langevin dynamics with general friction coefficient is straightforward, and we will not pursue such generality herein for simplicity.

Assumption 1.1. In this work, we shall only consider strongly convex $U$ with Lipschitz gradient, i.e., we consider the following family of potential functions,

\[
\mathcal{F} \equiv \mathcal{F}(d, \ell, L) := \left\{ U \in C^2(\mathbb{R}^d) \mid \ell \mathbb{I}_d \leq \nabla^2 U(x) \leq L \mathbb{I}_d, \forall x \in \mathbb{R}^d \right\}
\]

(1.2)
for fixed parameters $0 < \ell < L < \infty$. Under the strong convexity assumption, we know that $x^*$ is uniquely determined by $U$. The condition number $\kappa$ is defined as $\kappa := L/\ell$.

1.2. Main results. In the context of Langevin sampling, we assume that, besides the Brownian motion, the query to a weighted Brownian motion $\tilde{W}_t^\theta$ is also admissible, where

\[
\tilde{W}_t^\theta := \int_0^t e^{\theta s} \, dW_s.
\]

(1.3)
When $\theta = 0$, $\tilde{W}_t^{(\theta=0)} \equiv W_t$. In general, we define a correlated Gaussian process

\[
\tilde{W}_t^\theta := (\tilde{W}_t^{\theta_1}, \ldots, \tilde{W}_t^{\theta_j}, \ldots, \tilde{W}_t^{\theta_J}),
\]

as a short-hand notation. In particular, we shall use $\tilde{W}_t^{(0,2)} \equiv (W_t, \tilde{W}_t^{(2)})$ frequently below, as in our main theorem. The reason for such an assumption is that in the context of Langevin sampling, generating correlated Gaussian random vectors is not computationally expensive, whereas computing $\nabla U$ is usually the computational bottleneck.

Our main result is the following information-based complexity bound for solving the underdamped Langevin dynamics with $U \in \mathcal{F}$. 

Theorem 1.2 (Information-based complexity with queries to $\nabla U$ and weighted Brownian motions). Consider the complexity problem $\mathcal{F}$ (1.2) with the following set of admissible information

$$\Lambda := \left\{ (\nabla U(x), \tilde{W}_t^{(0,2)}) \mid x \in \mathbb{R}^d, \ t \in [0,T] \right\},$$

then whenever $N \geq N_0$ for some integer $N_0$ (independent of the dimension $d$),

$$C_{\text{low}} \sqrt{dN} N^{-3/2} \lesssim \inf_{A \in \mathcal{A}_{\text{rand}}^N} e_{\mathcal{F},\Lambda}(A) \lesssim C_{\text{up}} \sqrt{dN} N^{-3/2},$$

where the prefactor $C_{\text{up}} = \sqrt{\frac{L}{\ell} + \frac{\ell}{L}}$, and $C_{\text{low}} \equiv C_{\text{low}}(\ell, L, T)$ can be chosen as

$$C_{\text{low}} = \sup_{C_2 > 0, C_R > 0} \sqrt{\mathcal{P}(C_x, C_v, u, T)C_2^2 \min\{u - \ell, u_R - u\} \mathcal{C}(C_x, C_v, u_R, L, T)},$$

where $\mathcal{P}(C_x, C_v, u, T)$ for $\ell \leq u \leq L$ is defined below in (2.8), and $\mathcal{C}(C_x, C_v, u_R, L, T)$ for $\ell \leq u_R \leq L$ is defined below in (3.4).

As a remark, the choice of $\tilde{W}_t^{(0,2)}$ for the admissible information $\Lambda$ (in particular, the weighted Brownian motion $\tilde{W}_t^{(2)}$) comes from the special choice of the friction coefficient in the underdamped Langevin dynamics (1.1). In the above, $e_{\mathcal{F},\Lambda}(A)$ is the worst $L^2$ strong error for any algorithm $A$, defined later in (2.3); the notation $\mathcal{A}_{\text{rand}}^N$ means the set of randomized algorithms that use $N$ queries of $\nabla U$ and $N$ queries of $\tilde{W}_t^{(0,2)}$. The notion of randomized algorithms using only $N$ queries will be elaborated further in Sec. 2.1 below. The proof of Theorem 1.2 will be given in Sec. 3. The proof of the lower bound estimate is based on a novel non-asymptotic perturbation result with respect to the potential $U$ (see Proposition 3.3).

Remark 1.3.

(i) As a corollary to the theorem, the randomized midpoint method (see (2.5) below for the algorithm) is order optimal.

(ii) The fundamental challenge for the computational problem $(\mathcal{F}, \Lambda)$ comes from the insufficient information of $\nabla U$, instead of the path irregularity of the random process $\tilde{W}_t^{(0,2)}$. Therefore, $\tilde{W}_t^{(0,2)}$ does not play as a bottleneck in proving the lower bound estimate in Theorem 1.2. However, if we replace $\tilde{W}_t^{(0,2)}$ in the admissible information $\Lambda$ (1.4) by $W_t$ only (the Brownian motion itself), then the complexity lower bound becomes $\Omega(\sqrt{dN}^{-1})$, as the irregularity of the Brownian motion $W_t$ becomes the complexity bottleneck. This follows from the classical result by Clark and Cameron [6] (see also the literature review in the next subsection).

(iii) If we replace $\mathcal{F}$ in (1.2) by the following larger set of potentials

$$\left\{ U \in C^1(\mathbb{R}^d) \mid \ell \leq \frac{\| \nabla U(x) - \nabla U(y) \|_2}{\| x - y \|_2} \leq L, \ \forall x \neq y \in \mathbb{R}^d \right\},$$

the above lower bound in (1.5) also holds, by the definition of $e_{\mathcal{F},\Lambda}$ (2.3).

(iv) In (1.6), the scaling of $C_{\text{low}}$ with respect to the time $T$ and the condition number $\kappa = L/\ell$ is complicated. Providing a tight estimate of $C_{\text{low}}$ appears to be rather challenging, and we shall leave it to future works.

(v) Though we focus on underdamped Langevin dynamics in this paper, the ideas and techniques herein are applicable to a wide range of SDEs.
1.3. Literature review. Below is a brief literature review for underdamped Langevin algorithms and also the information-based complexity for differential equations.

Underdamped Langevin algorithms. The Euler-Maruyama method for the underdamped Langevin dynamics, which replaces \( \nabla U(X_t) \) with \( \nabla U(X_{kh}) \) in (1.1) and solves the modified equation for a short time \( h \) at the \( k \)th time step, is the most widely studied algorithm. To the best of our knowledge, it was first proposed and studied by Ermak and Buckholz \[11\]. Cheng, Chatterji, Bartlett, and Jordan \[5\] and later Dalalyan and Riou-Durand \[7\] proved that the strong error of the Euler-Maruyama algorithm is \( \mathcal{O}(\sqrt{dN}^{-1}) \). Results were generalized to non-convex potentials in \[4\] with the same rate in \( d \) and \( N \) but with much worse prefactors. The sampling error of the Euler-Maruyama algorithm in Kullback–Leibler divergence was studied in \[32\]. Recently, Shen and Lee \[50\] proposed the randomized midpoint method, which reduces the error to \( \mathcal{O}(\sqrt{dN}^{-3/2}) \). There have been other algorithms, for example, the BBK scheme \[2, 42\], the Verlet-type scheme proposed in \[13\], and the Leimkuhler-Matthews scheme \[31\], but non-asymptotic analysis has not been studied for these yet.

Information-based complexity for differential equations. We now provide a concise review of related works on the information-based complexity for both ordinary and stochastic differential equations.

Information-based complexity analysis for ODEs was initially studied by Kacewicz \[23, 24, 25, 26\] for deterministic algorithms, and later by Kacewicz \[27, 28\], Heinrich and Milla \[15\], and Daun \[8\] for randomized algorithms. For some particular classes of ODE systems, the matching complexity bounds and order-optimal algorithms are well known, for both deterministic and randomized algorithms. A notable observation is that compared to deterministic algorithms, randomized algorithms may achieve order \( 1/2 \) speed-up, which relates to the universal convergence rate of Monte Carlo methods. This phenomenon also occurs for solving SDE in our case: compared to the Euler-Maruyama method, the randomized midpoint method \[50\] achieves order \( 1/2 \) improvement. On the other hand, we shall comment that it is still open whether such an improvement is non-trivial in our problem by employing randomized algorithms, namely, whether there exists a strong order \( 3/2 \) deterministic algorithm with only gradient queries.

As for the information-based complexity result for SDEs, the lack of full information about both drift and diffusion terms might contribute to the overall computational complexity. It is a common practice to study the complexity from drift and diffusion separately. Therefore, most works in the literature focus on the complexity due to the diffusion term, since the complexity of the drift term (with trivial diffusion term) reduces to the ODE problem. However, in our problem, it appears unlikely to reduce the problem into analyzing the drift and diffusion terms separately, because both terms are non-trivial for the computational problem in \( \mathcal{F} \) (1.2). As far as we know, our problem does not fit into known IBC problem formulations for SDEs.

The study of the information-based complexity for the diffusion part dates back at least to the seminal work of Clark and Cameron \[6\]. They considered SDEs with \( C^3 \) drift term (with bounded derivatives up to the third-order) and constant diffusion term, and they proved that the strong one-point approximation error is asymptotically \( \Omega(N^{-1}) \), for algorithms with uniform mesh grids, where \( N \) is the number of queries to the Brownian motion \( W_t \) \[6, Theorem 1\]. The order optimal algorithm is simply the Euler-Maruyama method \[44, 16\]. Clark and Cameron also showed that for general SDEs with the Lipschitz diffusion term, a certain family of algorithms
with uniform mesh grid will result in the one-point approximation error with order \( \Omega(N^{-1/2}) \) [6]. The minimum one-point approximation error for scalar SDEs could be found in [39]. Apart from the one-point approximation error, the error for trajectories is also considered, i.e., the global approximation error. A series of works of Hofmann, Müller-Gronbach, and Ritter, addressed this problem for \( L^2 \) error [18, 20, 17], and for \( L^\infty \) error [19, 38]. We refer readers to a survey paper by Müller-Gronbach and Ritter [40] for more details. Around the last decade, Przybyłowicz [45, 46, 47], Przybyłowicz and Morkisz [48] studied the time-irregular SDEs. More recently, Hefter, Herzwurm, and Müller-Gronbach provided probabilistic lower bound estimates [14].

Finally, we also point out other related works studying differential equations with inexact information, see, e.g., [29, 1] for ODEs and [36, 37] for SDEs.

**Notation.** The Lebesgue measure on \( \mathbb{R}^d \) (for any dimension \( d \)) is denoted by \( \mu \). The probability space for (1.1) is \( (\mathcal{M}, \Sigma, P) \) and the probability space for randomized algorithms is \( (\mathcal{M}, \Sigma, \tilde{P}) \). When \( cf \leq g \) for some universal constant \( c \), we denote this by \( f \preceq g \) as a simplification; the notation \( \succeq \) is similarly defined. The notations \( \Omega \) and \( \mathcal{O} \) follow the convention in complexity analysis, i.e., \( f = \Omega(g) \) means \( f \succeq g \), and \( f = \mathcal{O}(g) \) means \( f \preceq g \). The binary relations \( \prec \) and \( \succ \) are partial order relations on the Boolean lattice \( \{0, 1\}^N \).

2. Preliminaries. In this section, we will illustrate the setup of the IBC problem under consideration, the integral form of (1.1), the randomized midpoint method [50], and the exact solution of (1.1) for 1D quadratic potentials.

2.1. IBC problem setup. We have explained the family of computational problem, characterized by the family \( \mathcal{F} \) (1.2) in the introduction. Next, we shall explain more about the admissible information and the family of randomized algorithms. We refer readers to e.g., [40, Sec. 2] for a more abstract framework.

**Admissible information.** The set of admissible information \( \Lambda \) (1.4), recalled here

\[
\Lambda := \left\{ \left( \nabla U(x), \tilde{W}^{(0,2)}_t \right) \mid x \in \mathbb{R}^d, \ t \in [0, T] \right\},
\]

means we only have finite queries to both \( \tilde{W}^{(0,2)}_t \) and \( \nabla U \). We need to use finite amount of information to predict the strong solution \( X_T(U, \omega) \) in (1.1), and such a prediction is known as an algorithm.

**Algorithms.** A deterministic algorithm \( A \) is a map from given information to approximate \( X_T(U, \omega) \), i.e.,

\[
X_T(U, \omega) \approx A \left( \nabla U(Y_1(\omega)), \nabla U(Y_2(\omega)), \cdots, \nabla U(Y_N(\omega)), \tilde{W}^{(0,2)}_{t_1(\omega)}(\omega), \tilde{W}^{(0,2)}_{t_2(\omega)}(\omega), \cdots, \tilde{W}^{(0,2)}_{t_N(\omega)}(\omega) \right),
\]

where random variables \( Y_j(\omega) \) and \( t_j(\omega) \) could be chosen in an adaptive way: if we introduce

\[
\Phi_j := \left( \nabla U(Y_1(\omega)), \nabla U(Y_2(\omega)), \cdots, \nabla U(Y_j(\omega)), \tilde{W}^{(0,2)}_{t_1(\omega)}(\omega), \tilde{W}^{(0,2)}_{t_2(\omega)}(\omega), \cdots, \tilde{W}^{(0,2)}_{t_j(\omega)}(\omega) \right) \in (\mathbb{R}^d \times \mathbb{R}^{2d})^j,
\]

then there is a map \( \varphi_j : (\mathbb{R}^d \times \mathbb{R}^{2d})^j \to \mathbb{R}^d \times \mathbb{R} \) such that \( (Y_{j+1}(\omega), t_{j+1}(\omega)) := \varphi_j(\Phi_j) \); we set \( (Y_0(\omega), t_0(\omega)) \equiv (x^*, 0) \). The family of all such algorithms is denoted by \( \mathcal{A}^{\text{Det}}_N \).
The family of randomized algorithms is denoted by $A^{\text{Rand}}_N$. For a randomized algorithm $A \in A^{\text{Rand}}_N$, there is correspondingly a probability space $(\tilde{M}, \tilde{\Sigma}, \tilde{P})$, independent of the probability space for the underdamped Langevin dynamics $(M, \Sigma, P)$, and randomized algorithms are random variables $A : \tilde{M} \to A^{\text{Det}}_N$; for each $\tilde{\omega} \in \tilde{M}$, $A_{\tilde{\omega}} \in A^{\text{Det}}_N$. Apparently, $A^{\text{Det}}_N \subseteq A^{\text{Rand}}_N$ and moreover, $A^{\text{Det}}_{N_1} \subseteq A^{\text{Rand}}_{N_2}$ whenever $N_1 \leq N_2$. Therefore, to analyze randomized algorithms for underdamped Langevin dynamics, the probability space that we really need to consider is

$$\tilde{M} \times M,$$

with the probability measure $\tilde{P} \times P$.

The error of the randomized algorithm $A_{\tilde{\omega}} : \tilde{M} \to A^{\text{Det}}_N$ is measured in the $L^2$ sense herein:

$$e_{F, A}(A) := \sup_{U \in \mathcal{F}} \left( \mathbb{E}_{\tilde{\omega}, \tilde{\omega}} \left[ |X_T(U, \omega) - A_{\tilde{\omega}}(U, \omega)|^2 \right] \right)^{1/2},$$

where $X_T(U, \omega)$ denotes the strong solution of (1.1) at time $T$, for a given potential function $U$, and $A_{\tilde{\omega}}(U, \omega)$ denotes the numerical approximation of $X_T(U, \omega)$. Recall that the initial condition is fixed for a given $U$, thus the strong solution $X_T(\cdot, \omega)$ is totally determined by $U$.

**Remark 2.1.** For the underdamped Langevin dynamics used to sample log-concave probability distributions $e^{-U}/\int e^{-U}$, we are interested only in $X_T$, instead of the whole trajectory on the interval $[0, T]$.

### 2.2. The integral form and the randomized midpoint method.

Several numerical algorithms for underdamped Langevin dynamics [11, 5, 7, 50] are based on its integral form

$$X_t = X_0 + \frac{1 - e^{-2t}}{2} V_0 + \frac{1}{\sqrt{L}} \int_0^t (1 - e^{2(s-t)}) \, dW_s - \frac{1}{2L} \int_0^t (1 - e^{2(s-t)}) \nabla U(X_s) \, ds,$$

$$V_t = e^{-2t} V_0 + \frac{2}{\sqrt{L}} \int_0^t e^{2(s-t)} \, dW_s - \frac{1}{L} \int_0^t e^{2(s-t)} \nabla U(X_s) \, ds.$$

In [50], Shen and Lee considered a randomized midpoint method for simulating underdamped Langevin dynamics, in the context of sampling log-concave distributions. Given $X_k$ and $V_k$ at time $t_k := kh$, where $h$ is the time step size, the randomized midpoint method approximates $\hat{X}_{k+1}$ and $\hat{V}_{k+1}$ in the following way:

$$\hat{X}_{k+1} = \dot{X}_k + \frac{1 - e^{-2h}}{2} \dot{V}_k + \frac{1}{\sqrt{L}} \int_0^h (1 - e^{2(s-h)}) \, dW_{k+s}$$

$$- \frac{1}{2L} h(1 - e^{2(h-h)}) \nabla U(\hat{X}_{k+1/2}),$$

$$\hat{V}_{k+1} = e^{-2h} \dot{V}_k + \frac{2}{\sqrt{L}} \int_0^h e^{2(s-h)} \, dW_{k+s}$$

$$- \frac{1}{L} he^{2(h-h)} \nabla U(\hat{X}_{k+1/2}),$$

$$\hat{X}_{k+1/2} = \dot{X}_k + \frac{1 - e^{-2h}}{2} \dot{V}_k + \frac{1}{\sqrt{L}} \int_0^h (1 - e^{2(s-h)}) \, dW_{k+s}$$

$$- \frac{1}{2L} \int_0^h (1 - e^{2(s-h)}) \, ds \nabla U(\hat{X}_k),$$

$$\dot{X}_{k+1/2} = \dot{V}_{k+1} - \frac{1}{L} \int_0^h e^{2(s-h)} \, ds \nabla U(\hat{X}_{k+1/2}),$$

$$\dot{V}_{k+1} = e^{-2h} \dot{V}_k + \frac{2}{\sqrt{L}} \int_0^h e^{2(s-h)} \, dW_{k+s}$$

$$- \frac{1}{L} \int_0^h e^{2(s-h)} \, ds \nabla U(\hat{X}_{k+1/2}).$$
where the random variable $\eta$ is uniformly distributed on the interval $[0,1]$, independent of $W_t$.

In the above, $\hat{X}_{k+1}$ and $\hat{V}_{k+1}$ are obtained by approximating the integral with respect to $\nabla U(X_s)$ in (2.4) by its evaluation at a single point $\hat{X}_{k+1/2}$; $\hat{X}_{k+1/2}$ is obtained using the Euler-Maruyama scheme for the integral form (2.4) at the random time $t_k + \eta h$.

Many previous works have proposed and analyzed various randomized algorithms to solve differential equations. For ODEs, the analogy of the randomized midpoint method can be found in, e.g., [15, 8, 1]. More randomized ODE solvers could be found in e.g., [22, 51, 52]. As for SDEs, the randomized Euler’s method, which is in a very similar spirit as the randomized midpoint method, has been studied in, e.g., [48, 46, 47, 36]. A randomized Milstein method was studied by Kruse and Wu [30] for non-differentiable drift functions; a randomized derivative-free Milstein method was studied by Morkisz and Przybyłowicz [37] for scalar SDEs with inexact information.

Remark 2.2. While we focus on the strong error in this paper, we would like to comment that for underdamped Langevin dynamics, the randomized midpoint method defined in (2.5) has a weak error of $O(h^3)$. As the full analysis is tedious and it is not the main focus of our paper, we only include a heuristic argument here.

Note that for a fixed realization of $W_t$, we can compare

$$
\hat{X}_1 - X_h = -\frac{1}{2L} \left( h(1 - e^{-2(h-\eta h)}) \nabla U(\hat{X}_h) - \int_0^h (1 - e^{-2(h-s)}) \nabla U(X_s) \, ds \right)
$$

$$
= -\frac{1}{2L} \left( h(1 - e^{-2(h-\eta h)}) \nabla U(\hat{X}_h) - h(1 - e^{-2(h-\eta h)}) \nabla U(X_{\eta h}) 
+ h(1 - e^{-2(h-\eta h)}) \nabla U(X_{\eta h}) - \int_0^h (1 - e^{-2(h-s)}) \nabla U(X_s) \, ds \right),
$$

$$
\hat{V}_1 - V_h = -\frac{1}{L} \left( h e^{-2(h-\eta h)} \nabla U(\hat{X}_h) - \int_0^h e^{-2(h-s)} \nabla U(X_s) \, ds \right)
$$

$$
= -\frac{1}{L} \left( h e^{-2(h-\eta h)} \nabla U(\hat{X}_h) - h e^{-2(h-\eta h)} \nabla U(X_{\eta h}) \right)
- \frac{1}{L} \left( h e^{-2(h-\eta h)} \nabla U(X_{\eta h}) - \int_0^h e^{-2(h-s)} \nabla U(X_s) \, ds \right)
=: I + II.
$$

We observe that $\hat{X}_1 - X_h$ is of higher order than $\hat{V}_1 - V_h$. Therefore, keeping only the error from $V$ and by the Taylor expansion around $(X_h, V_h)$, we can estimate, for a smooth enough test function $f$, that

$$
|\mathbb{E}[f(\hat{X}_1, \hat{V}_1) - f(X_h, V_h)]| \lesssim |\mathbb{E}[\nabla_v f(X_h, V_h) \cdot (I + II)]| 
+ |\mathbb{E}[(I + II) \cdot \nabla_v^2 f(X_h, V_h)(I + II)]|.
$$

Then we use facts that $(X_h, V_h)$ is independent of $\eta$ and $\mathbb{E}[II] = 0$,

$$
|\mathbb{E}[f(\hat{X}_1, \hat{V}_1) - f(X_h, V_h)]| \lesssim \frac{h}{L} \left[ |\mathbb{E}[\nabla_v f(X_h, V_h) \cdot (\nabla U(\hat{X}_h) - \nabla U(X_{\eta h}))]| 
+ \mathbb{E}[|\nabla_v^2 f(X_h, V_h)|||\hat{V}_1 - V_h|^2] \right].
$$
Finally, assuming that all derivatives of \( f \) are bounded, we use [50, Lemma 9] for the first term below, and [50, Lemma 2] for the second term below,

\[
|\mathbb{E}(f(\hat{X}_1, \hat{V}_1) - f(X_h, V_h))| \lesssim \frac{h}{L} (\mathbb{E}|\nabla U(\hat{X}_1) - \nabla U(X_{qh})|^2)^{\frac{1}{2}} + \mathbb{E}|\hat{V}_1 - V_h|^2 = \mathcal{O}(h^4).
\]

This local truncation error gives \( \mathcal{O}(h^3) \) weak error by Grönwall’s inequality as usual.

### 2.3. Exact solution for quadratic potentials in 1D.

Our estimate of the prefactor \( C_{\text{low}} \) in Theorem 1.2 relies on the tail probability of \( X_t(U_u, \omega) \) and \( V_t(U_u, \omega) \), where the potential has the quadratic form \( U_u(x) := ux^2/2 \) (thus \( x^* = 0 \) for this case). Therefore, in this subsection, we shall first review the exact solution of the underdamped Langevin dynamics under quadratic potentials and then define a tail probability to be used later.

It is easy to rewrite (1.1) as

\[
d\begin{bmatrix} X_t \\ V_t \end{bmatrix} = H \begin{bmatrix} X_t \\ V_t \end{bmatrix} dt + \begin{bmatrix} 0 \\ \frac{2}{\sqrt{L}} \end{bmatrix} dW_t, \quad H = \begin{bmatrix} 0 & 1 \\ \frac{-2}{L} & -2 \end{bmatrix}.
\]

Then its integral form can be immediately obtained as follows

\[
\begin{bmatrix} X_t \\ V_t \end{bmatrix} = \int_0^t e^{H(t-s)} \begin{bmatrix} 0 \\ \frac{1}{\sqrt{L}} \end{bmatrix} dW_s.
\]

The matrix exponential of \( H \) can be explicitly computed, which leads to the following result.

**Lemma 2.3** (Exact solution). When \( d = 1 \) and \( U_u(x) = ux^2/2 \), we have

\[
\begin{align*}
X_t(U_u, \omega) &= \frac{1}{\sqrt{L} - u} \int_0^t \left( e^{-(t-s)\lambda_-} - e^{-(t-s)\lambda_+} \right) dW_s, \\
V_t(U_u, \omega) &= \frac{1}{\sqrt{L} - u} \int_0^t \left( -\lambda_- e^{-(t-s)\lambda_-} + \lambda_+ e^{-(t-s)\lambda_+} \right) dW_s,
\end{align*}
\]

where

\[
\lambda_{\pm} = 1 \pm \sqrt{1 - u/L}.
\]

Next, let us introduce the following quantity for \( C_x, C_v > 0, \ell \leq u \leq L, \)

\[
P(C_x, C_v, u, T) := \mathbb{P} \left( \omega : \sup_{0 \leq t \leq T} X_t(U_u, \omega) \geq 2C_x, \quad \inf_{0 \leq t \leq T} X_t(U_u, \omega) \leq -2C_x, \quad \sup_{0 \leq t \leq T} |V_t(U_u, \omega)| \leq C_v/2 \right).
\]

The event under consideration requires \( X_t(U_u, \omega) \) to fluctuate between \(-2C_x \) and \( 2C_x \), whereas the velocity \( V_t(U_u, \omega) \) is uniformly bounded, over the whole interval \([0, T]\). Typically, we should expect to choose a small \( C_x \) and a large \( C_v \) in order to have \( P(C_x, C_v, u, T) = \mathcal{O}(1) \). Indeed, if \( C_x/C_v \) is too large, the probability \( P(C_x, C_v, u, T) \) might be trivial, as stated in the following lemma.

**Lemma 2.4.** When \( 12C_x/C_v > T \), then \( P(C_x, C_v, u, T) = 0 \).

**Proof.** For any \( \omega \) satisfying the condition in (2.8), the travel distance of \( X_t \) must be at least \( 6C_x \) (since it starts from 0 and has to cross levels \( 2C_x \) and \(-2C_x\)) with velocity at most \( C_v/2 \), then the total time must be at least \( 12C_x/C_v \). \( \blacksquare \)
However, note that for large enough $C_v$,
\[
P(C_x, C_v, u, T) \geq \frac{1}{2} P \left( \omega : \sup_{0 \leq t \leq T} X_t(U_u, \omega) \geq 2C_x, \inf_{0 \leq t \leq T} X_t(U_u, \omega) \leq -2C_x \right) > 0.
\]
Therefore, the prefactor $C_{\text{low}}$ in (1.6) is non-zero. The precise dependence of $C_{\text{low}}$ on parameters $\ell$, $L$ and $T$, however, appears to be a challenging problem and will be left for future investigations.

3. Proof of Theorem 1.2. The proof of the lower bound estimate relies on the (non-asymptotic) perturbation analysis in Sec. 3.1, in particular, the lower bound estimate in Proposition 3.3. The overall strategy, from the information-based complexity perspective, is similar to the lower bound estimate for randomized algorithms for integration problems, see, e.g., [41]. The new ingredient is the perturbation type analysis for the particular problem under consideration. The proof of the upper bound is known from [50]. Thus, we shall only provide a sketch of the main steps to prove the upper bound for completeness.

3.1. Non-asymptotic perturbation analysis with respect to $U$. We consider the case $d = 1$, which is assumed throughout this subsection. We postpone proofs for all results in this subsection to Sec. 3.3 for clarity.

Let us consider
\[
U_u := \frac{ux^2}{2}, \forall u \in [\ell, L],
\]
and let us also introduce a set parameterized by $u \in (\ell, L)$ and $\epsilon > 0$
\[
\mathcal{F}_{u, \epsilon} := \{ U \in \mathcal{F} : \| \nabla U(x) - ux \|_{\infty} \leq \epsilon, x^*(U) = 0 \}.
\]
As a remark, for any $U \in \mathcal{F}_{u, \epsilon}$, we have the initial condition $X_0(U, \omega) = 0$.

First, we show that when the potential function is slightly perturbed away from a quadratic function $U_u$, the strong solutions of $X_t(U, \omega)$ and $V_t(U, \omega)$, are at most perturbed by an order of $O(\epsilon)$.

**Lemma 3.1 (Upper bound).** Consider $u \in (\ell, L)$. For any $U \in \mathcal{F}_{u, \epsilon}$, any $\omega \in \mathcal{M}$, and $t \in [0, T]$, we have
\[
|X_t(U, \omega) - X_t(U_u, \omega)| \leq \frac{\epsilon}{2L(1 - \sqrt{1 - \frac{u}{L}})\sqrt{1 - \frac{u}{L}}},
\]
\[
|V_t(U, \omega) - V_t(U_u, \omega)| \leq \frac{\epsilon}{L\sqrt{1 - \frac{u}{L}}}.
\]

(3.1)

For any $u \in (\ell, L)$, $C_x > 0$ and $C_v > 0$, let us define
\[
\bar{\epsilon} \equiv \bar{\epsilon}(C_x, C_v, u, L) := \min \left\{ 2L \left( 1 - \sqrt{1 - \frac{u}{L}} \right) \sqrt{1 - \frac{u}{L} C_x}, \frac{L C_v}{L - L/2} \right\},
\]
which is strictly positive. Moreover, for $\epsilon > 0$, let us define a set $\mathcal{E} \equiv \mathcal{E}(C_x, C_v, u, T, \epsilon)$
\[
\mathcal{E} := \left\{ \omega : \sup_{0 \leq t \leq T} X_t(U, \omega) \geq C_x, \inf_{0 \leq t \leq T} X_t(U, \omega) \leq -C_x, \sup_{0 \leq t \leq T} |V_t(U, \omega)| \leq C_v, \forall U \in \mathcal{F}_{u, \epsilon} \right\}.
\]

(3.2)
In the following lemma, we shall bound $\mathbb{P}(\mathcal{E})$ by $\mathbb{P}(C_x, C_v, u, T)$ from below, for small enough $\epsilon$.

**Lemma 3.2.** Consider any $u \in (\ell, L)$, and any $C_x, C_v > 0$. For arbitrary $0 < \epsilon < \bar{\epsilon}$, $\mathbb{P}(\mathcal{E})$ is uniformly bounded from below by $\mathbb{P}(C_x, C_v, u, T)$ defined in (2.8).

In general, for two fixed potential functions $U_1 \neq U_2$, the distance $|X_T(U_1, \omega) - X_T(U_2, \omega)|$ highly depends on the realization of the Brownian motion $\omega$, and it is unlikely to establish a uniform non-trivial lower bound of $|X_T(U_1, \omega) - X_T(U_2, \omega)|$ for arbitrary $\omega$. However, if we restrict the outcome $\omega$ to a “nice” set, i.e., $\omega \in \mathcal{E}$ defined in (3.2), then we can provide a lower bound estimate of $|X_T(U_1, \omega) - X_T(U_2, \omega)|$ as in the following Proposition. This lower bound estimate is the key to prove Theorem 1.2.

**Proposition 3.3.** Given $u \in (\ell, L)$, let $C_x, C_v, \epsilon, \mathcal{E}$ be the constants or the set defined above. Consider two potential functions $U_1, U_2 \in \mathcal{F}_{u, \epsilon}$. Assume that

(i) the continuous function $g(x) := \nabla U_1 - \nabla U_2$ is non-negative on $\mathbb{R}$;

(ii) there exists $I \subseteq [-C_x/2, C_x/2]$, a finite union of closed bounded intervals, such that

\[
(3.3) \quad g(x) \geq \frac{\epsilon}{2} \mathbb{1}_I(x), \quad \forall x \in \mathbb{R};
\]

Let us introduce $u_R \in [u, L]$ as a constant such that

\[
\nabla^2 U_2(x) \leq u_R, \quad \forall x \in \mathbb{R}.
\]

Then for any $\omega \in \mathcal{E}$, we have

\[
|X_T(U_1, \omega) - X_T(U_2, \omega)| \geq \overline{\epsilon} \mu(I),
\]

where $\mu$ is the Lebesgue measure and $\overline{\epsilon} \equiv \overline{\epsilon}(C_x, C_v, u_R, L, T)$ is given by

\[
(3.4) \quad \overline{\epsilon} := \begin{cases} 
\frac{e^{\frac{C_v \epsilon}{C_x} - T}(1 - \sqrt{1 - \frac{u}{L}})}{4LC_v \sqrt{1 - \frac{u}{L}}} \left(1 - e^{-\frac{C_v \epsilon}{C_x} \sqrt{1 - \frac{u}{L}}} \right), & \text{if } u_R < L; \\
\frac{C_x e^{\frac{C_v \epsilon}{C_x} - T}}{4LC_v^2}, & \text{if } u_R = L.
\end{cases}
\]

### 3.2. Proof of the lower bound estimate for Theorem 1.2

We shall proceed to prove the lower bound estimate, based on the results in Sec. 3.1.

**Case (I):** $d = 1$. We shall first consider the case $d = 1$.

*Step (1): Setup and notations.* Since we only access $\nabla U$ at $N$ points, we will not be able to gain the full information of $\nabla U$ based on the local queries. In this step, we shall consider a family of $U$ (see (3.6) and (3.7) below) as small perturbations of a quadratic potential with the mode (Hessian) $u$, and we shall estimate how the deviation of $\nabla U$ contributes to the error $\epsilon_{\mathcal{F}, A}(A)$ (2.3) for any randomized algorithm $A \in \mathcal{A}_N^{Rand}$.

Without loss of generality, we assume that $N$ is an even integer. We shall pick $\ell < u < u_R \leq L$. We could then fix $C_x$ and $C_v$ satisfying $\mathbb{P}(C_x, C_v, u, T) > 0$. Let us define

\[
(3.5) \quad \xi := \min\{u - \ell, u_R - u\} > 0, \quad \epsilon := \frac{C_v \xi}{8N}.
\]
We will pick \( N \) sufficiently large such that \( \epsilon < \varepsilon(C_x, C_u, u, L) \). Then we could also determine the set \( \mathcal{E} \) defined in (3.2).

We divide the interval \( I := \left[ -\frac{C_x}{N}, \frac{C_x}{N} \right] \) into \( 2N \) equally spaced sub-intervals. Let \( x_j = \frac{C_x}{2N} j \) for integers \(-N \leq j \leq N\) and let \( I_j = [x_j, x_{j+1}] \) for \(-N \leq j \leq N - 1\). Define a non-negative function \( g(x) \) on \( x \in \left[ 0, \frac{C_x}{2N} \right] \) by

\[
g(x) := \begin{cases} 
  ax^2, & x \in \left[ 0, \frac{C_x}{4N} \right]; \\
  -a(x - \frac{C_x}{4N})^2 + 2a\left(\frac{C_x}{8N}\right)^2, & x \in \left[ \frac{C_x}{8N}, \frac{3C_x}{8N} \right]; \\
  a(x - \frac{3C_x}{8N})^2, & x \in \left[ \frac{3C_x}{8N}, \frac{5C_x}{8N} \right], 
\end{cases}
\]

where \( a := \frac{\xi^4 N}{\epsilon^2} \). It is easy to verify that \( g \in C^1(\mathbb{R}) \) and moreover,

\[
\|g'\|_{\infty} = \xi, \quad \|g\|_{\infty} = \epsilon.
\]

Moreover, we choose \( \mathcal{I} = \left[ \frac{C_x}{8N}, \frac{3C_x}{8N} \right] \) (thus, length \( \mu(\mathcal{I}) = \frac{C_x}{4N} \)), and we know that \( g(x) \geq \frac{\xi^4}{8} \mathcal{I}(x) \).

For index \( \beta = (\beta_{-N}, \beta_{-N+1}, \ldots, \beta_{N-1}) \in \{0, 1\}^{2N} \), we define \( U_\beta \) with \( U_\beta(0) = 0 \) by its derivative

\[
\nabla U_\beta(x) := ux + \sum_{j=-N}^{N-1} \beta_j g(x - x_j) \geq ux + \sum_{j=-N}^{N-1} \beta_j \frac{\xi}{2} \mathcal{I}(x - x_j).
\]

Apparently, \( U_\beta \) is well-defined, \( U_\beta \in \mathcal{F}_{u, \epsilon} \), and \( \nabla^2 U_\beta(x) \leq u_R , \forall \beta, \forall x \in \mathbb{R} \). Define a space

\[
\mathcal{G} \equiv \mathcal{G}_{u, \epsilon} := \{ U_\beta : \beta \in \{0, 1\}^{2N} \} \subseteq \mathcal{F}_{u, \epsilon},
\]

and let \( \mu_\mathcal{G} \) be a uniform probability distribution on the set \( \mathcal{G} \), i.e., \( \mu_\mathcal{G}(U_\beta) = \frac{1}{2^{2N}} \) for any \( \beta \).

Then by definition (2.3),

\[
e_{\mathcal{F}, \Lambda}(A)^2 \geq \mathbb{E}_{\mu_\mathcal{G}} \mathbb{E}_{(\mathcal{G}, \omega) \sim \mathcal{P} \times \mathcal{P}} [ |X_T(U_\beta, \omega) - A_\mathcal{Z}(U_\beta, \omega) |^2 ]
\]

\[
= \mathbb{E}_{(\mathcal{G}, \omega) \sim \mathcal{P} \times \mathcal{P}} \left[ \mathbb{E}_{\mu_\mathcal{G}} [ |X_T(U_\beta, \omega) - A_\mathcal{Z}(U_\beta, \omega) |^2 ] \right]
\]

\[
\geq \mathbb{P}(\mathcal{E}) \mathbb{E}_{(\mathcal{G}, \omega) \sim \mathcal{P} \times \mathcal{P}} \left[ \mathbb{E}_{\mu_\mathcal{G}} [ |X_T(U_\beta, \omega) - A_\mathcal{Z}(U_\beta, \omega) |^2 ] \right],
\]

where \( \mathbb{P}_{\mathcal{E}} \) is the restricted probability measure of \( \mathbb{P} \) on the event \( \mathcal{E} \). We know that \( \mathbb{P}(\mathcal{E}) \) is uniformly bounded by a positive value \( \mathbb{P}(C_x, C_u, u, T) \) by Lemma 3.2, and we claim (to be proved below in the Step (2))

\[
\mathbb{E}_{\mu_\mathcal{G}} [ |X_T(U_\beta, \omega) - A_\mathcal{Z}(U_\beta, \omega) |^2 ] \geq \frac{C_x^2 C_u^2 \xi^2}{N^3}.
\]

Therefore,

\[
e_{\mathcal{F}, \Lambda}(A) \geq C_{\text{low}} N^{-3/2},
\]

where

\[
C_{\text{low}} = \sqrt{\mathbb{P}(C_x, C_u, u, T) C_x^2 C_u} \xi \overset{(3.5)}{=} \sqrt{\mathbb{P}(C_x, C_u, u, T) C_x^2 C_u} \min\{u - \ell, u_R - u\}.
\]
Since $C_x$, $C_v$, $u$, and $u_R$ are parameters to tune, we arrive at (1.6) by optimizing.

Step (2): Proof of the perturbation bound (3.9). From now on, we fix both $\bar{\omega} \in \mathbb{M}$ and $\omega \in \mathcal{E}$. The main task is to estimate the fluctuation of the exact solution $X_T(U_\beta, \omega)$ for those $U_\beta$ with the same algorithmic output $A_\omega(U_\beta, \omega)$ by Proposition 3.3; this is done by a quantitative perturbation analysis.

The first task is to characterize the set of $U_\beta$ with the same algorithmic output $A_\omega(U_\beta, \omega)$. This is given by Lemma 3.5 below. To state the result, let us define some notations. The access points for $\nabla U_\beta$ are denoted by $Y_1^\beta, Y_2^\beta, \ldots, Y_N^\beta$, which only depend on the choice of $\beta$. Let us denote the union of sub-intervals that $Y_j^\beta$ belong to as $\mathcal{J}^\beta$. If $\mu(\mathcal{J}^\beta) < C_x/2$ (i.e., there exist two indices $j_1 < j_2$ such that $Y_{j_1}^\beta$ and $Y_{j_2}^\beta$ belong to the same sub-interval), then we add sub-intervals with the largest indices to complete $\mathcal{J}^\beta$.

**Example 3.4.** If $N = 3$, then there are six sub-intervals $I_{-1}, I_{-2}, I_{-1}, I_0, I_1, I_2$. Let us consider the following examples:

- if all $Y_1^\beta, Y_2^\beta, Y_3^\beta \in I_0$, then we set $\mathcal{J}^\beta := I_0 \cup (I_1 \cup I_2)$;
- if all $Y_1^\beta, Y_2^\beta, Y_3^\beta \in I_{-1}$, then we set $\mathcal{J}^\beta := I_{-1} \cup (I_1 \cup I_2)$;
- if $Y_1^\beta, Y_2^\beta \in I_0$, and $Y_3^\beta \in I_1$, then we set $\mathcal{J}^\beta := I_0 \cup I_1 \cup (I_2)$;
- if $Y_1^\beta \in I_0$, $Y_2^\beta \in I_1$, and $Y_3^\beta \in I_2$, then we set $\mathcal{J}^\beta := I_0 \cup I_1 \cup I_2$.

The interval within the parenthesis is the additional sub-intervals that we add to complete $\mathcal{J}^\beta$.

Note that such a procedure is always valid, since $Y_1^\beta, Y_2^\beta, \ldots, Y_N^\beta$ reside in at most $N$ sub-intervals; for each $\beta$, $\mathcal{J}^\beta$ is always uniquely defined. From now on, when we use the notation $\mathcal{J}^\beta$, we refer to the “completed” version. Likewise, time points for queries, denoted by $t_j^\beta$, also depend on $\beta$ only.

**Lemma 3.5.** For any fixed index $\beta$, if for some index $\beta'$, $\nabla U_{\beta'}(x) = \nabla U_{\beta}(x)$ on the domain $x \in \mathcal{J}^\beta$, then

(i) $Y_j^\beta = Y_j^{\beta'}$, $t_j^\beta = t_j^{\beta'}$ for all $1 \leq j \leq N$;

(ii) $\mathcal{J}^\beta = \mathcal{J}^{\beta'}$ and moreover, $A_\omega(U_\beta, \omega) = A_\omega(U_{\beta'}, \omega)$.

**Proof.** Part (ii) trivially follows from the form of algorithms in (2.1) and part (i). Then it suffices to prove part (i). This comes from induction: if $Y_j^\beta = Y_j^{\beta'}, t_j^\beta = t_j^{\beta'}$ for all $j \leq k$, then the information up to $k$ queries are the same, i.e., $\Phi_k^\beta = \Phi_k^{\beta'}$ where $\Phi_k$ is defined in (2.2), and superscripts are used to indicate the dependence. Then $(Y_j^{\beta'}, t_{j+1}^{\beta'}) = \varphi_k(\Phi_k^{\beta'}) = Y_{k+1}^{\beta'}(t_{k+1}^{\beta'})$.

**Definition 3.6.** For two arbitrary indices $\beta$ and $\beta'$, we define a binary relation $\beta \sim \beta'$ if $\beta_j' = \beta_j$ whenever $I_j \subseteq \mathcal{J}^\beta$. By the above Lemma 3.5, we know $\mathcal{J}^\beta = \mathcal{J}^{\beta'}$ and $A_\omega(U_\beta, \omega) = A_\omega(U_{\beta'}, \omega)$. It is easy to verify that such a relation is an equivalence relation.

For any index $\beta$, apparently, there are exactly $2^N - 1$ other indices belonging to the same equivalence class (since we could freely choose $\beta_j \in \{0, 1\}$ whenever $I_j \not\subseteq \mathcal{J}^\beta$), and there are exactly $2^N$ such equivalence classes. Let us enumerate these equivalence classes by $K_1, K_2, \ldots, K_{2^N}$.

**Example 3.7.** When $N = 3$, for an index $\beta = (0, 0, 0, 0, 0, 0)$, we assume that $\mathcal{J}^\beta = I_0 \cup I_1 \cup I_2$ as an example. Then we could freely choose the first three indices, and the equivalence class containing $\beta$ is exactly $\{(0, 1)^3, 0, 0, 0\}$.
We now consider how much the actual solution $X_T(U_{\beta}, \omega)$ can fluctuate within the same class. Consider an arbitrary equivalence class $K$, and suppose $\beta \in K$. For any index $\beta'$, recall that $\mathcal{J}^{\beta'}$ are the same for all $\beta' \in K$ (i.e., $\mathcal{J}$ only depends on the equivalence class $K$ that we consider), and $\beta'_j$ are the same if $I_j \subseteq \mathcal{J}^{\beta}$. This motivates us to define the reduced index below.

**Definition 3.8 (Reduced index).** For an equivalence class $K$, suppose the corresponding union of sub-intervals is $\mathcal{J}$. We introduce the reduced index $\bar{\beta} := (\bar{\beta}_j)_{I_j \notin \mathcal{J}} \in \{0,1\}^N$. For each class $K$, there is a one-to-one correspondence between $\beta \in K$ and a reduced index $\bar{\beta} \in \{0,1\}^N$. Thus, we slightly abuse the notation and denote $U_{\bar{\beta}} \equiv U_{\beta}$, whenever the equivalence class $K$ is clear from the context. For the reduced index, we define a partial order $\succ$ as follows: if $\bar{\beta}'_j \geq \bar{\beta}_j$ for all $1 \leq j \leq N$ (namely, $\nabla U_{\bar{\beta}}(x) \geq \nabla U_{\beta}(x)$ for all $x \in \mathbb{R}$), then we denote $\bar{\beta}' \succ \bar{\beta}$ (or $\bar{\beta} \prec \bar{\beta}'$).

By Proposition 3.3 with $\mathcal{I} = \bigcup_{j \geq 1} \bar{\beta}_j > \bar{\beta}_j \cdot (x_j + \mathcal{J})$, we immediately have the following result.

**Lemma 3.9.** If $\bar{\beta}' \succ \bar{\beta}$, then

$$|X_T(U_{\bar{\beta}'}, \omega) - X_T(U_{\bar{\beta}}, \omega)| \geq \frac{C_T}{4N} \# \{ j : \bar{\beta}'_j > \bar{\beta}_j \}$$

(3.10)

$$= \frac{C_T^2C_\xi}{32N^2} \# \{ j : \bar{\beta}'_j > \bar{\beta}_j \}.$$

Let us introduce the following set, for any integer $0 \leq k \leq N$,

$$\mathcal{M}_k := \left\{ \bar{\beta} \in \{0,1\}^N : \sum_{j=1}^N \bar{\beta}_j = k \right\}.$$

**Lemma 3.10.** Assume that the even integer $N \geq 2$. For any integer $0 \leq k \leq N/2$, there exists a bijective map $\Upsilon : \mathcal{M}_k \rightarrow \mathcal{M}_{N-k}$ such that for any $\beta \in \mathcal{M}_k$, we have $\bar{\beta} \prec \Upsilon(\bar{\beta})$. In particular, when $k = N/2$, $\Upsilon(\bar{\beta}) = \bar{\beta}$.

**Proof.** This lemma follows immediately from the symmetric chain decomposition (SCD) for Boolean lattices; see, e.g., [12, 56] for an introduction, as well as proofs. A symmetric chain is a sequence $\gamma^{(n)} \prec \gamma^{(n+1)} \prec \cdots \prec \gamma^{(N-n)}$ where $\gamma^{(j)} \in \mathcal{M}_j$ for $n \leq j \leq N - n$. SCD states that the set $\{0,1\}^N$ can be decomposed into disjoint symmetric chains. Therefore, for any $\bar{\beta} \in \mathcal{M}_k$, it must belong to a particular chain, say $\gamma^{(n)} \prec \gamma^{(n+1)} \prec \cdots \prec \gamma^{(N-n)}$. By the definition of symmetric chains, we have $\gamma^{(k)} = \bar{\beta}$, and then we can simply define $\Upsilon(\bar{\beta}) := \gamma^{(N-k)} \succ \gamma^{(k)} \equiv \bar{\beta}$. Such a procedure is always valid, and since all symmetric chains are disjoint, $\Upsilon$ is a bijective map.

With these preparations, we can now continue to finish the proof of (3.9), and thus the lower bound in Theorem 1.2 for the case $d = 1$. Within any equivalence class
\[ \sum_{\beta \in \mathcal{K}} |X_T(U_{\beta}, \omega) - A_\omega(U_{\beta}, \omega)|^2 \]

\[ \geq \sum_{k=0}^{N-1} \sum_{\beta \in \mathcal{K}_k} |X_T(U_{\beta}, \omega) - A_\omega(U_{\beta}, \omega)|^2 + |X_T(U_{T(\beta)}, \omega) - A_\omega(U_{T(\beta)}, \omega)|^2 \]

\[ \geq C_2 C_2^2 \xi_2^2 \sum_{k=0}^{N} \left( \frac{N}{2} - k \right)^2 \geq \frac{C_2^2 C_2^2 \xi_2^2}{N^4} \cdot 2N. \]

Finally, we have

\[ E_{\mu_0} \left[ |X_T(U_{\beta}, \omega) - A_\omega(U_{\beta}, \omega)|^2 \right] = \frac{1}{24N} \sum_{k \in \mathcal{K}} \sum_{\beta \in \mathcal{K}_k} |X_T(U_{\beta}, \omega) - A_\omega(U_{\beta}, \omega)|^2 \]

\[ \geq \frac{1}{24N} \cdot 2N \cdot \frac{C_2^2 C_2^2 \xi_2^2}{N^4} \cdot 2N \geq \frac{C_2^2 C_2^2 \xi_2^2}{N^4}. \]

Thus we complete the proof of the lower bound in Theorem 1.2 for the case \( d = 1 \).

**Case (II): General dimension \( d \).** For a general dimension \( d \), we can choose \( U(X) = U(X_1, X_2, \cdots, X_d) = \sum_{j=1}^{d} U^{(j)}(X_j) \), where \( U^{(j)} : \mathbb{R} \to \mathbb{R} \) and \( X_j \in \mathbb{R} \). If \( U^{(j)} \in \mathcal{F}(1, \ell, L) \), then \( U \in \mathcal{F}(d, \ell, L) \). Note that if \( U \) takes this particular form, then each component of the underdamped Langevin dynamics (1.1) is evolving independently. Then we immediately know

\[ e_{\mathcal{F}, \Lambda}(A)^2 \geq E_{\omega, \omega} \left[ |X_T(U, \omega) - A_\omega(U, \omega)|^2 \right] \]

\[ = \sum_{j=1}^{d} E_{\omega, \omega} \left[ |X_T^{(j)}(U, \omega) - A_\omega^{(j)}(U, \omega)|^2 \right] \geq dC_{\text{low}}^2 N^{-3}, \]

where \( X_T^{(j)}(U, \omega) \in \mathbb{R} \) is the \( j \)-th component of \( X_T(U, \omega) \); \( A_\omega^{(j)}(U, \omega) \) is the \( j \)-th component of the algorithmic prediction \( A_\omega(U, \omega) \). Therefore, we obtain \( e_{\mathcal{F}, \Lambda}(A) \gtrsim C_{\text{low}} \sqrt{dN^{-3/2}} \). The last inequality above is intuitively reasonable, since \( A_\omega^{(j)}(U, \omega) \) could be regarded as an algorithm of the \( j \)-th component, and having queries to the information from independent components, like \( \nabla X_k U^{(k)}(X_k) \) \((k \neq j)\), would not improve the algorithmic prediction for the \( j \)-th component.

More rigorously, one could directly generalize the proof of the Case (I). Below is a sketch of the only few technical differences. First, similar to (3.8),

\[ e_{\mathcal{F}, \Lambda}(A)^2 \geq \sum_{j=1}^{d} E_{\omega, \omega} E_{\mu_{g_1} \times \mu_{g_2} \times \cdots \times \mu_{g_d}} \left[ |X_T^{(j)}(U, \omega) - A_\omega^{(j)}(U, \omega)|^2 \right], \]

where \( \mu_{g_j} \) is a uniform measure of \( U^{(j)}(X_j) \in \mathcal{G}_j \), similar to (3.7), for \( 1 \leq j \leq d \). Without loss of generality, we only need to consider the component \( j = 1 \), and we
Hence, by introducing $g$

$$|X_t^{(1)}(U, \omega) - A_s^{(1)}(U, \omega)|^2 \geq C_{\text{low}}^2 N^{-3}.$$  

We shall fix $\omega \in \mathcal{E}$, where $\mathcal{E}$ is now defined in the same way as (3.2) by considering the components $X_t^{(1)}(U, \omega)$ and $V_t^{(1)}(U, \omega)$ only. We shall also fix $\tilde{\omega} \in \tilde{\mathcal{M}}$ for $j \geq 2$. Then it suffices to prove that (cf. (3.9))

$$\mathbb{E}_{\mu_0} \left[ |X_t^{(1)}(U, \omega) - A_s^{(1)}(U, \omega)|^2 \right] \geq C_{\text{low}}^2 \xi^2.$$  

The proof of this inequality is essentially the same as the Step (2) in the Case (I). The only minor difference is that $\mathcal{J}^j$ is now defined as the completed union of sub-intervals where the first components of $Y_1^\beta, Y_2^\beta, \ldots, Y_N^\beta$ reside in.

### 3.3. Proof of results in Sec. 3.1.

**Proof of Lemma 3.1.** Let us introduce $g(x) := \nabla U(x) - u x$, $\Delta_{X,t} := X_t(U, \omega) - X_t(U_u, \omega)$, and $\Delta_{V,t} := V_t(U, \omega) - V_t(U_u, \omega)$. By assumption, $\|g\|_\infty \leq \epsilon$ and $\Delta_{X,0} = \Delta_{V,0} = 0$. By (1.1), it is straightforward to derive that

$$d \left[ \begin{array}{c} \Delta_{X,t} \\ \Delta_{V,t} \end{array} \right] = H \left[ \begin{array}{c} \Delta_{X,t} \\ \Delta_{V,t} \end{array} \right] dt + \left[ \begin{array}{c} 0 \\ -\frac{1}{\epsilon} g(X_t(U, \omega)) \end{array} \right] dt, \quad H = \left[ \begin{array}{cc} 0 & \frac{1}{T} \\ -\frac{1}{T} & -2 \end{array} \right].$$

Then we could rewrite the above equation in the integral form,

$$\left[ \begin{array}{c} \Delta_{X,t} \\ \Delta_{V,t} \end{array} \right] = \int_0^t e^{H(t-s)} \left[ \begin{array}{c} 0 \\ -g(X_s(U, \omega)) \end{array} \right] ds.$$  

Hence, by introducing $g_s \equiv g(X_s(U, \omega))$, and recalling $\lambda_{\pm}$ from (2.7), we have

$$\begin{align*}
\Delta_{X,t} &= -\frac{1}{2\sqrt{L(L-u)}} \int_0^t g_s(e^{-(t-s)\lambda_-} - e^{-(t-s)\lambda_+}) ds, \\
\Delta_{V,t} &= -\frac{1}{2\sqrt{L(L-u)}} \int_0^t g_s(\lambda_+ e^{-(t-s)\lambda_+} - \lambda_- e^{-(t-s)\lambda_-}) ds.
\end{align*}$$

Since $|g_s| \leq \epsilon$, it is straightforward to obtain that

$$\begin{align*}
|\Delta_{X,t}| &\leq \frac{\epsilon}{2\sqrt{L(L-u)}} \int_0^t |e^{-(t-s)\lambda_-} - e^{-(t-s)\lambda_+}| ds \\
&= \frac{\epsilon}{2\sqrt{L(L-u)}} \frac{1 - e^{-\lambda_- t} - 1 - e^{-\lambda_+ t}}{\lambda_- - \lambda_+} \\
&\leq \frac{\epsilon}{2\lambda_- \sqrt{L(L-u)}} = \frac{\epsilon}{2L(1 - \sqrt{1 - \frac{u}{L}}) \sqrt{1 - \frac{u}{L}}}.
\end{align*}$$

Similarly, for $|\Delta_{V,t}|$, we have

$$\begin{align*}
|\Delta_{V,t}| &\leq \frac{\epsilon}{2\sqrt{L(L-u)}} \int_0^t |\lambda_+ e^{-(t-s)\lambda_+} - \lambda_- e^{-(t-s)\lambda_-}| ds \\
&\leq \frac{\epsilon}{2\sqrt{L(L-u)}} \int_0^t \lambda_+ e^{-(t-s)\lambda_+} + \lambda_- e^{-(t-s)\lambda_-} ds \\
&= \frac{\epsilon}{2\sqrt{L(L-u)}} (1 - e^{-\lambda_+ t} + 1 - e^{-\lambda_- t}) \leq \frac{\epsilon}{L \sqrt{1 - \frac{u}{L}}}. \quad \Box
\end{align*}$$
Moreover, we could easily observe that $\ell$ here and below. For some value $\theta$ for

Finally, recall the expression of $P$ to observe that again denote $\eta$ and the source part. Suppose we have $0 \leq \epsilon < \delta$. Then by (3.1), and likewise for the other two cases. We have

Finally, recall the expression of $P(C_x, C_v, u, T)$ from (2.8).

**Proof of Lemma 3.2.** For any $C_x, C_v > 0$, let us pick any $0 < \epsilon < \delta$. Notice that

implies that $\sup_{0 \leq t \leq T} X_t(U, \omega) \geq C_x$ by (3.1), and likewise for the other two cases.

We shall fixed $\omega \in \mathcal{E}$ throughout this proof. Let $\Delta_{X,t} := X_t(U_1, \omega) - X_t(U_2, \omega)$ and $\Delta_{V,t} := V_t(U_1, \omega) - V_t(U_2, \omega).$ Then by (1.1), we have

with initial conditions $\Delta_{X,0} = \Delta_{V,0} = 0,$ where $u_t$ is a continuous function of time such that

To see why $u_t$ is a well-defined continuous function, notice that $U_2 \in \mathcal{F}$ is a $C^2(\mathbb{R})$ function (recall $\mathcal{F}$ in (1.2)). Then by the first-order Taylor’s expansion,

for some value $\vartheta$ between $X_t(U_1, \omega)$ and $X_t(U_2, \omega);$ we simply let $u_t = \nabla^2 U_2(\vartheta).$ Moreover, we could easily observe that $\ell \leq u_t \leq u_R \leq L.$ For simplicity, we shall again denote

here and below.

Intuitively, the ODE dynamics (3.12) consists of two parts: the contraction part and the source part. Suppose $u_t \equiv u$ is independent of the time, then it is easy to observe that $e^{\alpha t}$ is a contraction operator for large enough time $t,$ and the ODE dynamics (3.12) with $g \equiv 0$ will convergence to the origin exponentially fast, for any initial condition; the source part $-\frac{u}{L}$ will drag the velocity term (i.e., $\Delta_{V,t}$) towards the negative direction. Under the assumption that $\omega \in \mathcal{E},$ the term $g_t$ takes non-zero value at least for a period of $\mu(I)/C_v.$

When $u_t = u$ for all $t,$ (3.12) has an explicit solution shown below, similar to (2.6) and (3.11) above.
Lemma 3.11. Suppose \( u_t = u \) for all \( t \in [0,T] \) in (3.12), then \( \Delta_{X,T} = S(u,T) \), where
\[
S(u,T) := \left\{ \begin{array}{ll}
\int_0^T \frac{e^{(t-T)(1+\sqrt{1-u/L})} - e^{(t-T)(1-\sqrt{1-u/L})}}{2\sqrt{L} (L-u)} g_t \, dt, & \text{if } u \leq L; \\
\int_0^T \frac{(t-T)e^{t-T}}{L} g_t \, dt, & \text{if } u = L.
\end{array} \right.
\]
Observe that \( \Delta_{X,T} \leq 0 \) for both cases, which inspires us to propose the following general result.

Lemma 3.12. The region characterized by \( \Delta_{V,t} \leq -\Delta_{X,t} \) and \( \Delta_{X,t} \leq 0 \) forms a trapping region for the dynamics (3.12). Therefore, the quantity \( \Delta_{X,t} \equiv X(t,U_t,\omega) - X_t(U_t,\omega) \leq 0 \) for any \( t \in [0,T] \).

Proof. To prove that the region formed by \( \Delta_{V,t} \leq -\Delta_{X,t} \) and \( \Delta_{X,t} \leq 0 \) is a trapping region for the ODE dynamics (3.12), we consider the following three cases at the boundary:

- \( (\Delta_{X,t} = 0 \text{ and } \Delta_{V,t} = 0) \). We know \( \frac{d}{dt} \Delta_{X,t} = 0 \) and \( \frac{d}{dt} \Delta_{V,t} = -\frac{L}{u} g_t \leq 0 \).
  Thus, the solution of \( \Delta_{X,t} \) and \( \Delta_{V,t} \) will not escape the trapping region.

- \( (\Delta_{X,t} = 0 \text{ and } \Delta_{V,t} < 0, \text{i.e., the negative half line of the velocity-axis}) \). We know
  \[
  \left( \frac{d}{dt} \Delta_{X,t}, \frac{d}{dt} \Delta_{V,t} \right) \cdot (-1,0) = \left( \Delta_{V,t}, -2\Delta_{V,t} - \frac{g_t}{L} \right) \cdot (-1,0) = -\Delta_{V,t} > 0.
  \]
  Therefore, the solution of \( \Delta_{X,t} \) and \( \Delta_{V,t} \) will not escape the trapping region from the negative half-line of the velocity-axis.

- \( (\Delta_{V,t} = -\Delta_{X,t} \text{ for } \Delta_{X,t} < 0) \).
  \[
  \left( \frac{d}{dt} \Delta_{X,t}, \frac{d}{dt} \Delta_{V,t} \right) \cdot (-1,-1) = \left( \Delta_{V,t}, -\frac{u_t}{L} \Delta_{X,t} - 2\Delta_{V,t} - \frac{g_t}{L} \right) \cdot (-1,-1)
  = (u_t/L - 1)\Delta_{X,t} + \frac{g_t}{L} \geq 0.
  \]
  By summarizing the above three cases, we conclude that the region formed by \( \Delta_{V,t} \leq -\Delta_{X,t} \) and \( \Delta_{X,t} \leq 0 \) is indeed a trapping region. Since \( \Delta_{X,0} = \Delta_{V,0} = 0 \), we know that \( \Delta_{X,t} \leq 0 \) for any time \( t \geq 0 \).

By the above lemma (i.e., \( \Delta_{X,t} \leq 0 \) for any time \( t \in [0,T] \)), we know that
\[
\frac{d}{dt} \Delta_{X,t} = \Delta_{V,t},
\]
\[
\frac{d}{dt} \Delta_{V,t} = -\frac{u_t}{L} \Delta_{X,t} - 2\Delta_{V,t} - \frac{g_t}{L} \leq -\frac{u_R}{L} \Delta_{X,t} - 2\Delta_{V,t} - \frac{g_t}{L}.
\]

Lemma 3.13. We claim that in general,
\[
\Delta_{X,t} \leq S(u_R,T).
\]

Proof. Let \( (\Delta_{X,t}^{(1)}, \Delta_{V,t}^{(1)}) \) be the solution of (3.13), and let \( (\Delta_{X,t}^{(2)}, \Delta_{V,t}^{(2)}) \) be the solution of (3.12) for \( u_t \equiv u_R \). Then let us introduce \( \Gamma_{X,t} := \Delta_{X,t}^{(1)} - \Delta_{X,t}^{(2)} \) and \( \Gamma_{V,t} := \Delta_{V,t}^{(1)} - \Delta_{V,t}^{(2)} \). We immediately have
\[
\dot{\Gamma}_{X,t} = \Gamma_{V,t}, \quad \dot{\Gamma}_{V,t} \leq -\frac{u_R}{L} \Gamma_{X,t} - 2\Gamma_{V,t}.
\]
Since \( \Gamma_{X,0} = \Gamma_{V,0} = 0 \), by the same argument as in Lemma 3.12, we know that \( \Gamma_{X,t} \leq 0 \) for any \( t \geq 0 \). Therefore, \( \Delta^{(1)}_{X,t} \leq \Delta^{(2)}_{X,t} \equiv S(u_R, T) \).

Let us consider the case \( u_R < L \). Then we have

\[
|\Delta_{X,t}| = -\Delta_{X,t} \geq \int_0^T e^{(t-T)(1-\sqrt{1-u_R/L})} - e^{(t-T)(1+\sqrt{1-u_R/L})} \frac{g_t}{2\sqrt{L(L-u_R)}} dt
\]

\[
\geq \int_0^T e^{(t-T)(1-\sqrt{1-u_R/L})} \times \left(1 - e^{2(t-T)\sqrt{1-u_R/L}}\right) \mathbb{1}_I(X_t(U_1, \omega)) dt.
\]

Without loss of generality, we assume \( \tau_1(\omega) < \tau_2(\omega) \), where \( \tau_1 \) is the first hitting time of \( X_t(U_1, \omega) \) to \( -C_x \) and \( \tau_2 \) is the first hitting time to \( C_x \). Since we assume \( \omega \in \mathcal{E} \), both \( \tau_1 \) and \( \tau_2 \) are well-defined and \( 0 \leq \tau_1, \tau_2 \leq T \). Then

\[
|\Delta_{X,t}|
\geq \frac{\epsilon}{4L\sqrt{1 - \frac{u_R}{L}}} \int_{\tau_1}^{\tau_2} e^{(t-T)(1-\sqrt{1-u_R/L})} \left(1 - e^{2(t-T)\sqrt{1-u_R/L}}\right) \mathbb{1}_I(X_t(U_1, \omega)) dt
\]

\[
= \frac{\epsilon}{4L\sqrt{1 - \frac{u_R}{L}}} \int_{\tau_1 + \frac{\epsilon}{2C_v}}^{\tau_2 - \frac{\epsilon}{2C_v}} e^{(t-T)(1-\sqrt{1-u_R/L})} \left(1 - e^{2(t-T)\sqrt{1-u_R/L}}\right) \mathbb{1}_I(X_t(U_1, \omega)) dt
\]

\[
\geq \frac{\epsilon}{4L\sqrt{1 - \frac{u_R}{L}}} \int_{\tau_1 + \frac{\epsilon}{2C_v}}^{\tau_2 - \frac{\epsilon}{2C_v}} e^{(t-T)(1-\sqrt{1-u_R/L})} \mathbb{1}_I(X_t(U_1, \omega)) dt,
\]

where we use the following observation in the second equality: since the velocity \( V_t(U_1, \omega) \) is bounded by \( C_v \), starting from the time \( \tau_1 \) (note that \( X_{\tau_1}(U_1, \omega) = -C_x \)), it takes at least \( C_x/(2C_v) \) amount of time to reach \( -C_x/2 \). Thus, we have \( \mathbb{1}_I(X_t(U_1, \omega)) = 0 \) for \( t \in [\tau_1, \tau_1 + \frac{\epsilon}{2C_v}] \) by the assumption (ii) that \( \mathcal{I} \subseteq [-C_x/2, C_x/2] \) (similarly for the time period \( [\tau_2 - \frac{\epsilon}{2C_v}, \tau_2] \)).

By the fact that \( \mu(t : X_t(U_1, \omega) \in \mathcal{I}) \geq \frac{\mu(I)}{C_v} \) (namely, \( \mathbb{1}_I(X_t(U_1, \omega)) = 1 \) for at
least $\mu(I)/C_v$ period of time), we have

$$|\Delta_{X,T}| \geq \frac{\epsilon (1 - e^{\frac{-C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}} L \sqrt{1 - \frac{\mu(I)}{C_v}})}{4L \int_{\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L}}^{\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L} + T} e^{(t-T)(1-\sqrt{1-\frac{\mu(I)}{C_v}})} \, dt$$

$$\geq \frac{\epsilon (1 - e^{\frac{-C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}} L \sqrt{1 - \frac{\mu(I)}{C_v}})}{4L \int_{\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L}}^{\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L} + T} e^{(t-T)(1-\sqrt{1-\frac{\mu(I)}{C_v}})} \, dt}$$

$$= \frac{\epsilon (1 - e^{\frac{-C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}} L \sqrt{1 - \frac{\mu(I)}{C_v}})}{4L \sqrt{1 - \frac{\mu(I)}{C_v}}} e^{(\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L} - T)(1-\sqrt{1-\frac{\mu(I)}{C_v}})} \frac{e^{\frac{\mu(I)}{C_v}(1-\sqrt{1-\frac{\mu(I)}{C_v}})} - 1}{1 - \sqrt{1-\frac{\mu(I)}{C_v}}}$$

$$\geq \frac{\epsilon \mu(I) (1 - e^{\frac{-C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}} L \sqrt{1 - \frac{\mu(I)}{C_v}})}{4LC_v \sqrt{1 - \frac{\mu(I)}{C_v}}} e^{(\tau_1 + \frac{C_v \sqrt{1 - \frac{\mu(I)}{C_v}}}{L} - T)(1-\sqrt{1-\frac{\mu(I)}{C_v}})}$$

where to get the final inequality, we use the fact that $\tau_1 \geq \frac{C_v}{\sqrt{\mu(I)}}$ by the same velocity-type argument. Then we finish the proof for the case $u_R < L$. As for $u_R = L$, one could simply pass the limit $u_R \to L$ and then obtain the expression of $\bar{C}$.

**3.4. Proof of the upper bound estimate for Theorem 1.2.** The upper bound estimate is based on Ref. [50]. In the following, we shall provide a sketch only. We consider non-adaptive mesh grid, i.e., $t_j = jh$ with $h = T/N$ as in [50].

Suppose $\bar{X}_n$, $\bar{X}_{n+1/2}$ and $\bar{V}_n$ are given by the randomized midpoint method as in (2.5), and suppose $\bar{X}_{n+1}$ and $\bar{V}_{n+1}$ are the exact solutions at time $t_{n+1}$, given $\bar{X}_n$ and $\bar{V}_n$ at time $t_n$. By [50, Appendix E], we have

$$E[\|\bar{X}_N - X_t\|^2 + \|\bar{X}_N + \bar{V}_N - X_{t_N} - V_{t_N}\|^2]$$

$$\leq e^{-\frac{N}{2h}} E[\|\bar{X}_N - X_t\|^2 + \|\bar{X}_0 + \bar{V}_0 - X_0 - V_0\|^2]$$

$$+ \frac{2\kappa}{h} \sum_{n=1}^{N} \left( 3E[\|\bar{X}_n - \bar{X}_n\|^2] + 2E[\|\bar{V}_n - \bar{V}_n\|^2] \right)$$

$$+ \sum_{n=1}^{N} \left( 3E[\|\bar{X}_n - \bar{X}_n\|^2] + 2E[\|\bar{V}_n - \bar{V}_n\|^2] \right)$$

$$= \frac{2\kappa}{h} \sum_{n=1}^{N} \left( 3E[\|\bar{X}_n - \bar{X}_n\|^2] + 2E[\|\bar{V}_n - \bar{V}_n\|^2] \right)$$

$$+ \sum_{n=1}^{N} \left( 3E[\|\bar{X}_n - \bar{X}_n\|^2] + 2E[\|\bar{V}_n - \bar{V}_n\|^2] \right),$$

where in the last step, we use the fact that $\bar{X}_0 = X_0$ and $\bar{V}_0 = V_0$. 

**RANDOMIZED ALGORITHMS FOR UNDERDAMPED LANGEVIN DYNAMICS**
By \cite[Lemma 2]{50}, we have
\[
\mathbb{E}[\|\hat{X}_N - X_{t_N}\|^2 + \|\hat{X}_N + \hat{V}_N - X_{t_N} - V_{t_N}\|^2] \\
\lesssim \frac{2\kappa}{h} \left( h^8 \sum_{n=0}^{N-1} \mathbb{E}[\|\hat{V}_n\|^2] + \frac{h^{10}}{L^2} \sum_{n=0}^{N-1} \mathbb{E}[\|\nabla U(\hat{x}_n)\|^2] + \frac{Ndh^9}{L} \right) \\
+ h^4 \sum_{n=0}^{N-1} \mathbb{E}[\|\hat{V}_n\|^2] + \frac{h^4}{L^2} \sum_{n=0}^{N-1} \mathbb{E}[\|\nabla U(\hat{x}_n)\|^2] + \frac{Ndh^5}{L} \\
\lesssim (h^4 + h^7\kappa) \sum_{n=0}^{N-1} \mathbb{E}[\|\hat{V}_n\|^2] + \left( \frac{h^9}{L\ell} + \frac{h^4}{L} \right) \sum_{n=0}^{N-1} \mathbb{E}[\|\nabla U(\hat{x}_n)\|^2] + \left( \frac{Ndh^8}{L\ell} + \frac{Ndh^5}{L} \right).
\]

Next, we use \cite[Lemma 12]{50}, and obtain that
\[
\mathbb{E}[\|\hat{X}_N - X_{t_N}\|^2 + \|\hat{X}_N + \hat{V}_N - X_{t_N} - V_{t_N}\|^2] \\
\lesssim (h^4 + h^7\kappa) \left( \frac{Nd}{L} + \frac{1}{L} \mathbb{E}[\|\nabla U(\hat{x}_N), \hat{V}_N\|] \right) \\
+ \left( \frac{h^9}{L\ell} + \frac{h^4}{L^2} \right) \left( N\ell d + \frac{L}{\ell} \mathbb{E}[\|\nabla U(\hat{x}_N), \hat{V}_N\|] \right) + \left( \frac{Ndh^8}{L\ell} + \frac{Ndh^5}{L} \right) \\
\lesssim \frac{h^4}{L} \left( \mathbb{E}[\|\nabla U(\hat{x}_N), \hat{V}_N\|] \right) + \frac{h^4Nd}{L}.
\]

where in the last step, we use the fact that we are working on the $L^2$ strong error estimate and $h$ is the small parameter herein. Then we need to estimate $\mathbb{E}[\|\nabla U(\hat{x}_N), \hat{V}_N\|]$. Similar to \cite[Appendix E]{50},
\[
\mathbb{E}[\|\nabla U(\hat{x}_N), \hat{V}_N\|] \\
\lesssim L\mathbb{E}[\|\hat{V}_N - V_{t_N}\|^2 + \|\hat{x}_N - X_{t_N}\|^2] + L\mathbb{E}[\|V_{t_N}\|^2] + \frac{1}{L} \mathbb{E}[\|\nabla U(X_{t_N})\|^2] \\
\lesssim L\mathbb{E}[\|\hat{x}_N - X_{t_N}\|^2 + \|\hat{V}_N + \hat{V}_N - X_{t_N} - V_{t_N}\|^2] \\
+ L\mathbb{E}[\|V_{t_N}\|^2] + \frac{1}{L} \mathbb{E}[\|\nabla U(X_{t_N})\|^2].
\]

By combining the last two equations,
\[
\mathbb{E}[\|\hat{x}_N - X_{t_N}\|^2] \leq \mathbb{E}[\|\hat{x}_N - X_{t_N}\|^2 + \|\hat{x}_N + \hat{V}_N - X_{t_N} - V_{t_N}\|^2] \\
\lesssim \frac{h^4}{L} \left( L\mathbb{E}[\|V_{t_N}\|^2] + \frac{1}{L} \mathbb{E}[\|\nabla U(X_{t_N})\|^2] \right) + \frac{h^4Nd}{L} \\
\lesssim h^4 \left( \mathbb{E}[\|V_{t_N}\|^2] + \mathbb{E}[\|X_{t_N} - x^*\|^2] \right) + \frac{h^4Nd}{L}.
\]

Suppose $(Y_t, Z_t)$ is another solution of the underdamped Langevin dynamics (1.1) with the initial distribution as $\rho_{\infty}$. Then similar to \cite[Appendix E]{50},
\[
\mathbb{E}[\|V_{t_N}\|^2] + \mathbb{E}[\|X_{t_N} - x^*\|^2] \\
\lesssim \mathbb{E}[\|V_{t_N} - Z_{t_N}\|^2 + \|X_{t_N} - Y_{t_N}\|^2] + \mathbb{E}[\|Z_{t_N}\|^2] + \mathbb{E}[\|Y_{t_N} - x^*\|^2] \\
\lesssim \mathbb{E}[\|V_{t_N} - Z_{t_N} + X_{t_N} - Y_{t_N}\|^2 + \|X_{t_N} - Y_{t_N}\|^2] + \frac{d}{L} + \frac{d}{\ell} \\
\lesssim e^{-\frac{\ell}{2}} \mathbb{E}[\|V_0 - Z_0 + X_0 - Y_0\|^2 + \|X_0 - Y_0\|^2] + \frac{d}{L} + \frac{d}{\ell} \lesssim \left( e^{-\frac{\ell}{2}} + 1 \right) \frac{d}{\ell} \lesssim \frac{d}{L}. 
\]
Finally, we have
\[ E[\|\hat{X}_N - X_{t_N}\|^2] \lesssim \frac{dh^3}{\ell} + \frac{h^4Nd}{L} \lesssim \frac{d}{N^3} \left( \frac{T^3}{\ell} + \frac{T^4}{L} \right). \]
Thus, if the algorithm \( A \) is the randomized midpoint method (2.5),
\[ e_{F,A}(A) \lesssim C_{up} \sqrt{dn}^{-3/2}, \]
where \( C_{up} = \sqrt{T^3/\ell + T^4/L} \).

Acknowledgments. We would like to thank Sam Hopkins (University of Minnesota) for introducing the symmetric chain decomposition [21].
