# Introduction and Summary

Rebecca M. Henderson and Richard G. Newell

---

Reorienting current energy systems toward a far greater reliance on technologies with low or no carbon dioxide emissions is an immense challenge. Fossil fuels such as oil, coal, and natural gas together satisfy 81 percent of global energy demand and generate 69 percent of global anthropogenic greenhouse gas (GHG) emissions (International Energy Agency [IEA] 2009). Moreover, worldwide demand for energy is expected to increase by about 40 percent over the next twenty years, with most of this increase occurring in non-Organization for Economic Cooperation and Development (OECD) countries (IEA 2009, EIA 2010).

Meeting this demand without significantly increasing global emissions using currently available technology would be costly. For example, the IEA projects that about \$26 trillion of investment in energy-supply infrastructure will be needed over the 2008 to 2030 period simply to meet projected increases in energy demand (IEA 2009).<sup>1</sup> Modeling scenarios of cost-effective global climate mitigation policy suggest that, for atmospheric stabilization targets in the range of 450 to 550 parts per million (ppm) CO<sub>2</sub>, the cost of GHG mitigation through 2050 *without significant innovation in the underlying technologies* would require additional trillions or tens of tril-

Rebecca M. Henderson is the Senator John Heinz Professor of Environmental Management at Harvard Business School, and a research associate of the National Bureau of Economic Research. Richard G. Newell completed his work on this chapter as the Gendell Associate Professor of Energy and Environmental Economics at Duke University's Nicholas School of Environment, when he was also a research associate at the National Bureau of Economic Research and a University Fellow at Resources for the Future. He is currently on leave from Duke University as administrator of the U.S. Energy Information Administration (EIA).

1. This figure does not include expenditures on energy demand-side technologies (e.g., transportation, appliances, and equipment), investment demand for which will measure in the trillions of dollars each year.

1 lions of dollars (Newell 2008). Longer-term total costs through 2100 could  
2 be approximately double this amount.

3 Plausible developments in energy efficiency, bioenergy, wind, solar, nuclear  
4 and low-emitting fossil fuel technologies could greatly reduce these costs.  
5 For example, Edmonds et al. (2007) suggest that significant innovation could  
6 reduce the present-value cost of achieving CO<sub>2</sub> stabilization at 550 ppm by  
7 more than \$20 trillion. Other studies have found that the cumulative costs  
8 of achieving any given stabilization target are reduced by 50 percent or more  
9 under advanced technology scenarios (see, e.g., Manne and Richels 1992;  
10 Clarke et al. 2006). Accelerating innovation and technology adoption in  
11 energy is, thus, crucial to meeting greenhouse gas mitigation goals.

12 Given this urgency, it is not surprising that a flood of recent books and  
13 articles have explored how the U.S. energy innovation system could be  
14 improved (see, for example, work by Anadon and Holdren 2009; Gallagher,  
15 Holdren, and Sagar 2006; Anadon, Gallagher, and Bunn 2009; Grübler,  
16 Nakićenović, and Victor 1999; Lester 2009; Narayanamurti, Anadon, and  
17 Sagar 2009a, b; Newell 2008; Nemet and Kammen 2007; Ogden, Podesta,  
18 and Deutch 2008; and Weiss and Bonvillian 2009). By and large, this is  
19 tightly argued and persuasive work that is a critically important starting  
20 point for anyone interested in effective energy policy. This book explores the  
21 same questions using a complementary approach. Instead of focusing on  
22 the history of the energy industry to draw lessons for the future of energy  
23 innovation, it explores the history of innovation in several industries that  
24 have already seen extraordinary rates of technological progress: agriculture,  
25 chemicals, semiconductors, computers, the Internet, and biopharmaceuti-  
26 cals. Each of the chapters that follow explores the complex role that public  
27 policy and private markets have played in triggering rapid innovation in  
28 the industry and in sustaining it once in motion. Each industry differs from  
29 the energy sector in important ways, but we nonetheless believe that this  
30 approach provides a useful complement to the existing literature.

31 In the first place, the history of each industry reminds us that relatively  
32 rapid, transformational innovation can occur. Innovation in agriculture  
33 was a critical factor in reducing the manpower needed to grow the nation's  
34 crops from 49 percent of the U.S. workforce in 1880 to less than 2 percent  
35 in 2000. The chemical industry created entirely new materials and fuels, lay-  
36 ing the foundation both for progress in existing industries—as in the case  
37 of synthetic pesticides and fertilizers—and for the creation of entirely new  
38 ones, including plastics and synthetic fibers. Innovation in the information  
39 technology (IT) industry appears to have greatly increased the productivity  
40 of the U.S. economy: Jorgenson (2004) estimates that the quality-adjusted  
41 price of computers dropped at an annual average of 16 percent during 1959  
42 to 2001 and that this rate of decline doubled after the mid-1990s, while  
43 Berndt and Rappaport (2001) report that personal computer prices declined  
44 an average of 35 percent *a year* between 1992 and 2002. The Internet has

1 clearly changed all our lives, and the net effect of IT and telecommunications  
2 investment on national productivity appears to be quite high (Brynjolfsson  
3 and Hitt 2003; Jorgenson and Stiroh 2000). In the case of life sciences, major  
4 breakthroughs in areas such as heart disease, cancer, and Human Immuno-  
5 deficiency Virus (HIV) have significantly reduced mortality rates (Cockburn  
6 2007; Lichtenberg 2005; Duggan and Evans 2008). In each of these cases—  
7 with the possible exception of chemicals—well-funded, well-managed federal  
8 research laid the foundation for an industry that created great prosperity  
9 and that continues to be dominated by American firms.

10 The second reason why we believe that exploring the history of innovation  
11 in other industries may be useful is that it provides an intriguing perspec-  
12 tive on some of the policy recommendations currently being advanced for  
13 the energy industry. Taken together, the histories point to three key factors  
14 as critical to accelerating innovation: (a) well-funded, carefully man-  
15 aged public research that is tightly linked to the private sector; (b) rapidly  
16 growing demand; and (c) antitrust, intellectual property, and standards  
17 policies that together promote vigorous competition and the entry of new  
18 firms. Expressed at this level of generality, these results echo the funda-  
19 mental findings of an innovation policy literature that stretches back to  
20 Vannevar Bush (1945). Many scholars have noted the critical role played  
21 by well-managed federal research funds in shaping the United States’  
22 most innovative industries, and the idea that effective innovation feeds off  
23 both technology “supply” and market “demand” is a well-established one  
24 (Mowery and Rosenberg 1979). The innovation policy literature has focused  
25 less on the role of competition and new entrants in shaping innovation,  
26 but the intuition that new firms may have a critical role in spurring innova-  
27 tion goes back to Schumpeter (1934) and has recently been confirmed in a  
28 number of important studies (Aghion et al. 2005; Aghion et al. 2009). They  
29 are also broadly consistent with the bulk of the recommendations currently  
30 being made for accelerating innovation in energy.

31 But in innovation policy, the devil is in the details—particularly in the  
32 details of organizational implementation—and conclusions at this level of  
33 generality abstract from the critical institutional detail that is characteristic  
34 of each industry and that is particularly well captured in the chapters. The  
35 energy policy literature stresses the importance of adequate federal fund-  
36 ing and the development of tight linkages between the public and private  
37 sectors (Anadon and Holdren 2009; Gallagher, Holdren, and Sagar 2006;  
38 Anadon, Gallagher, and Bunn 2009; Lester 2009). It explores the critically  
39 important role of designing policy instruments that will support demand  
40 for low-carbon technologies (Newell 2008; Nemet and Kammen 2007) and  
41 the potential role of intellectual property regimes in shaping innovation  
42 diffusion (Sagar and Anadon 2009). But, most important, it stresses the  
43 critical need for the development of a comprehensive innovation strategy  
44 that can coordinate policy across multiple entities and for the design of insti-

1 tutional structures that ensure public money does not become pork (Lester  
2 2009; Ogden, Podesta, and Deutch 2008; National Commission on Energy  
3 Policy [NCEP] 2009; Weiss and Bonvillian 2009). In presenting the detailed  
4 histories of five industries where the delicate balance between public funding  
5 and private markets was maintained productively for many years, we hope to  
6 contribute in an important way to the conversation about exactly *how* these  
7 kinds of strategic and organizational choices can best be made.

8 Similarly, much of the current energy innovation policy literature stress  
9 the potential importance of public funding of “deployment”—or of sup-  
10 porting the initial implementation of new energy technologies given their  
11 probable risk and scale. In four of the industries discussed here—agricul-  
12 ture, semiconductors, computers, and the Internet—the federal government  
13 played an important role in funding deployment of the new technology.  
14 Again, in presenting detailed case examples of the variety of ways in which  
15 the federal government filled this role, we hope to stimulate useful debate  
16 about what might be most appropriate in the case of energy.

17 A comparison between contemporary prescriptions for energy innova-  
18 tion and the history of accelerated innovation in a range of other industries  
19 is also intriguing because it highlights a number of cases in which the two  
20 are significantly different. The current energy policy literature, for example,  
21 focuses much more on innovation “supply” (public and private funding for  
22 research) and on innovation “demand” (the use of policy instruments to  
23 create demand for low-carbon energy) than it does on the instruments of  
24 competition policy. One of the striking findings from our industry histories,  
25 for example, is the (often seemingly unintended) role of antitrust and pro-  
26 curement policy in enabling widespread entry into the innovating industry.  
27 The histories also stress the important role that federally funded research has  
28 played in generating highly trained human capital for the private sector, an  
29 issue that has been stressed in some of the current energy innovation policy  
30 literature (Newell 2008, 2010), but not broadly so.

31 The remainder of this introduction frames the volume by attempting to  
32 draw together some of the key themes that occur across the chapters. The  
33 book then opens with Richard G. Newell’s brief overview of the history of  
34 innovation in energy. The energy sector is vast and highly complex, but none-  
35 theless Newell sketches out some “central tendencies” that provide impor-  
36 tant background for the chapters that follow. In chapter 2, Tiffany Shih and  
37 Brian Wright describe the history of innovation in agriculture, an industry  
38 that—in its time—had the scale and reach of the energy sector in our own  
39 day and in which both local funding for diffusion and federally funded inno-  
40 vation proved to be critical. Their chapter also raises a number of important  
41 issues around the role of intellectual property rights and public or private  
42 partnership in framing innovation. In chapter 3, Ashish Arora and Alfonso  
43 Gambardella explore the sources of innovation in the chemical industry, an  
44 industry that resembles some aspects of the energy sector in the chemical

1 industry's focus on process development and whose early development was  
2 significantly more global than those of the others discussed here. Chapter  
3 4 presents Iain M. Cockburn, Scott Stern, and Jack Zausner's review of the  
4 roots of innovation in life sciences, an industry that has been the second-  
5 largest recipient of federal research funding (after defense) and that is justly  
6 celebrated for the extraordinary productivity of the "innovation ecosystem"  
7 that links its public and private sectors.

8 Chapter 5 moves to David C. Mowery's review of the innovative history  
9 of the computer and semiconductor industries, and in chapter 6, Shane  
10 Greenstein discusses the institutional roots of the innovations that led to the  
11 development of the Internet. Given the centrality of information technology  
12 and telecommunications to the modern economy, it is particularly intriguing  
13 to be reminded of the critically important role that the federal government  
14 played in the development of both sectors—and to be exposed to careful  
15 discussions of the institutional structures and strategic decisions that made  
16 public support so very powerful in both industries. Finally, in chapter 7,  
17 Josh Lerner concludes the book with a detailed focus on venture capital, one  
18 often-cited potential solution to the clean energy innovation problem. He  
19 notes that despite the fact that venture capital investments are a relatively  
20 small share of total research and development (R&D) investment, they are  
21 exceedingly effective. However, he notes that while public policy can help to  
22 maintain a healthy level of venture capital investment, direct government  
23 investment in venture capital funding can exacerbate the boom and bust  
24 cycles characteristic of the industry.

25 Taken together, these chapters do not provide a comprehensive review  
26 of innovation policy because several excellent reviews of innovation policy  
27 exist (see, for example, Branscomb and Keller 1999; Cohen and Noll 1991;  
28 Mowery and Nelson 1999). Neither are they a comprehensive history of  
29 modern industrial innovation or of innovation policy. We were unable to  
30 persuade an expert on the history of innovation in the space or defense  
31 industries to participate in the project, for example, and with the notable  
32 exception of the chapters on agriculture and chemicals, the accounts by  
33 and large focus on the history of innovation in the United States. Mowery,  
34 Nelson, and Martin (2009) focus particularly on the history of innovation  
35 in the United Kingdom and on the relevance of the Manhattan and Apollo  
36 projects for our understanding of energy policy, and their paper is highly  
37 recommended. We believe, however, that given the centrality of the indus-  
38 tries we explore to modern economic growth and the critical role of U.S.  
39 public policy in supporting each of them, our focus still yields important  
40 insights.

41 Last, we do not attempt to draw policy recommendations. This is in keep-  
42 ing with longstanding National Bureau of Economic Research (NBER)  
43 policy—but it also reflects our awareness that the energy sector is impor-  
44 tantly different from the industries discussed here. We hope instead to pro-

1 vide the kind of rich data that will allow the interested reader to draw his or  
2 her own conclusions.

### 3 4 **The Book's Key Themes**

5  
6 In broad outline, the chapters highlight three mechanisms that have his-  
7 torically served to support accelerated innovation: substantial, sustained,  
8 and effectively managed federal funding for fundamental research; the  
9 generation of growing customer demand, either through procurement or  
10 through the market; and the enabling of aggressive competition, particularly  
11 from newly entering firms.

### 12 **Public Support for Fundamental Research**

13  
14 The hypothesis that one of the central roles of public policy with respect  
15 to innovation is to fund “basic” research is a well-established idea in the  
16 innovation policy literature (Bush 1945) and rests on the observation that  
17 the benefits of truly fundamental research are, in general, very difficult for  
18 private firms to appropriate. Much of the existing energy innovation policy  
19 literature stresses the central importance of this issue for U.S. innovation  
20 policy, stressing the relatively low levels of federal funding for fundamental  
21 energy research (Gallagher, Holdren, and Sager 2006; Nemet and Kammen  
22 2007; Newell 2008; Ogden, Podesta, and Deutch 2008).

23 Publicly funded energy research constitutes about 3 percent of the total  
24 federal R&D budget (or less than 0.03 percent of gross domestic product  
25 [GDP]). Annual energy R&D funding decreased by more than half from  
26 a high of about \$9 billion (real 2009 dollars) in the late 1970s to about  
27 \$3 billion by the mid-1990s, where it remained for over a decade (see figure  
28 I.1; Newell 2008). This represented a drop from about 25 percent to 7 per-  
29 cent of nondefense federal R&D spending. Very recently, this trend has re-  
30 versed: the allocation to energy research increased by over 20 percent, sur-  
31 passing \$4 billion in 2007, although this still represented less than 4 percent  
32 of total federal R&D spending. Energy R&D budgets increased modestly  
33 again in 2008, and in 2009 grew dramatically as a result of spending under  
34 the American Recovery and Reinvestment Act in response to the economic  
35 downturn. (Note that the Recovery Act spending includes significant  
36 amounts for technology demonstration projects.) While the Recovery Act  
37 spending represents a short-lived event, regular appropriations for energy  
38 R&D are slated to increase to about \$6 billion by 2011, and the Obama  
39 administration has sought to further increase funding for basic research.

40 The most significant trend in recent years in federal R&D spending has  
41 been the large rise in defense R&D and in health-related R&D, which has  
42 increased from 25 percent of the federal nondefense R&D budget in 1980  
43 to 54 percent in 2007 (see figure I.2). To place these figures in some perspec-  
44 tive, in 2006, health expenditures accounted for 16 percent of GDP, energy

**Fig. I.1 U.S. federal energy RD&D spending (1974–2009, with estimates for 2010–2011)**

Sources: IEA (2010) U.S. Department of Energy (2010) for 2010 to 2011 estimates.

**Fig. I.2 U.S. federal R&D spending by budget function (1955–2008)**

Source: NSF Science Indicators (2009, <http://www.nsf.gov/statistics/fedbudget/>).

1 expenditures accounted for 8 to 9 percent of GDP in recent years, and agri-  
2 culture accounted for about 1 percent of GDP in 2004 (Newell 2008).

3 Faced with these numbers, many analysts have suggested very significantly  
4 increasing federal commitment to fundamental energy research (Gallagher,  
5 Holden, and Sager 2006; Nemet and Kammen 2007; Newell 2008; Ogden,  
6 Podesta, and Deutch 2008).

7 This idea is certainly consistent with the histories presented in our chap-  
8 ters. In every industry that we review, public support for fundamental re-  
9 search appears to have played a critical role in accelerating innovation in the  
10 industry, and there is some evidence that it has generated extraordinarily  
11 high returns. For example, Shih and Wright (chapter 2) suggest that mar-  
12 ginal returns to public research in agriculture have been on the order of 45  
13 to 60 percent. Similarly, Cockburn, Stern, and Zausner (chapter 4) highlight  
14 high, stable levels of public support as the primary foundation of industry's  
15 success in the life sciences, suggesting that this funding has led not only to  
16 many of the fundamental advances in scientific knowledge that have been  
17 indispensable to advances in modern molecular biology, but that it has also  
18 underwritten the development of a wide range of critical tools and tech-  
19 niques. For example, federal R&D underwrote the gene-splicing technique  
20 pioneered by Stanley Cohen and Herbert Boyer in 1973 that opened up the  
21 modern field of genetic engineering. Federal support for R&D was also criti-  
22 cal to the early history of the semiconductor and computer industries.

23 For example, Mowery (chapter 5) notes that although the first solid state  
24 transistor was developed privately by AT&T, the firm's invention built on  
25 an extensive program of government-funded wartime research and that at  
26 the time it occurred, AT&T was in a competitive race with a publicly funded  
27 effort at Purdue University. Early work in the computer industry was entirely  
28 government funded, and from 1949 to 1959, federal funds were nearly 60 per-  
29 cent of computer-related R&D spending. Even as private spending grew  
30 more important on a percentage basis, federal funding continued to in-  
31 crease, with federally funded basic research in computer science growing  
32 from \$65 million in 1976 to \$265 million in nominal dollars in 1995. The  
33 early development of the Internet rested entirely on federal funding of the  
34 seemingly obscure technology of large-scale packet switching—a tech-  
35 nology that was part of a portfolio of research whose commercial applica-  
36 tions were entirely unknown at the time. Even in the case of chemicals—an  
37 industry in which many critical scientific discoveries were made in private  
38 firms—much of the foundational science of the field was performed inside  
39 universities.

40 Each of our authors suggests, however, that it is not only the magnitude  
41 of the public commitment to research funding that is critical, but also the  
42 ways in which this funding is governed. In this respect, the results we pres-  
43 ent here are very much consistent with those in the energy innovation policy  
44 community who have stressed that it is not enough for the federal govern-

1 ment to dramatically increase funding for fundamental research: it is also  
2 critical that this research be managed appropriately (Lester 2009; Newell  
3 2008; Ogden, Podesta, and Deutch 2008).

4 Four themes in particular emerge from the following chapters. First, in  
5 every industry, with the possible exception of chemicals, federal support for  
6 fundamental research was sustained over long periods of time. In both agri-  
7 culture and life sciences, our authors explicitly point out that it took at least  
8 twenty years for fundamental research to have a notable effect on practice  
9 and that it is the “stock” of knowledge, not the flow, that has the greatest  
10 impact on accelerating private-sector innovation. For example, Shih and  
11 Wright note that it took several decades of development and learning before  
12 the U.S. land grant/State Agricultural Extension Service (SAES) system had  
13 acquired the scientific capacity and research base necessary to become an  
14 efficient system of innovation, and Cockburn, Scott, and Zausner suggest  
15 that the recent “surge and retreat” in National Institutes of Health (NIH)  
16 funding over the last decade has probably resulted in a less-productive inno-  
17 vation system and significantly distorted researcher incentives and career  
18 dynamics. In the case of IT, the groundbreaking investments were made in  
19 the 1940s and 1950s, but IT did not have a significant effect on the productiv-  
20 ity of the economy until the 1990s. These examples suggest that a sustained  
21 investment in energy innovation may have groundbreaking implications—  
22 but that it may be years before these investments bear their full fruit.

23 Second, every author explores in some detail the ways in which effective  
24 governance steered a middle course between public funding of research that  
25 is so abstract and removed from potential application that it becomes iso-  
26 lated from practice and the danger that public funds become so applied that  
27 they will substitute for private funds. This is an old concern in the technology  
28 policy literature (Cohen and Noll 1991) and one that particularly concerns  
29 analysts of energy innovation policy (Newell, chapter 1 in this volume).

30 For example, Shih and Wright highlight the important role that locally  
31 supported, locally sited extension stations have played in ensuring that pub-  
32 lic funding for agriculture has been closely linked to actual practice. At the  
33 same time, they cite a 1986 analysis of a public/private research effort in  
34 Canada’s malting barley industry in which the authors estimate that social  
35 gains would have been 40 percent higher if the public researchers had fo-  
36 cused only on more fundamental research. Arora and Gambardella, in their  
37 study of the chemical industry, highlight ways in which tight links between  
38 U.S. universities and the private sector have been instrumental in codifying  
39 and diffusing scientific advances made by the industry.

40 In the case of the life sciences, Cockburn, Stern, and Zausner note that  
41 federally funded research is administered overwhelmingly through investi-  
42 gator initiated, peer-reviewed processes that are expected to ensure that the  
43 resources are allocated to genuinely promising scientific opportunities. Peer-  
44 review processes are not without their drawbacks, but they have the great

1 advantage of putting every proposal through a rigorous “quality control”  
2 process controlled by experts in the field and, thus, of increasing the odds  
3 that the research will contribute meaningfully to the body of fundamental  
4 science. The authors stress, however, that the tight links that typically exist  
5 between public and private researchers in this sector serve to mitigate the  
6 risk that publicly funded research will become too removed from the prob-  
7 lems and issues that are likely to have real-world application. Many publicly  
8 funded researchers work closely with private companies, and many privately  
9 funded researchers publish widely in the public literature and participate in  
10 academic conferences.

11 In the case of the Internet, in contrast, Greenstein stresses the unique role  
12 of Defense Advanced Research Project Agency (DARPA) in enabling fun-  
13 damental, leading-edge research unencumbered by broader peer review. He  
14 focuses particular attention on DARPA’s practice of funding “wild ducks”—  
15 creative researchers who were not constrained by institutional expectations.  
16 He also details the importance of involving a wide variety of researchers  
17 from many different backgrounds. Furthermore, program officers relied not  
18 only on their own deep knowledge of the technology in making critical fund-  
19 ing decisions, but also on constantly bringing the network of researchers  
20 together to share ideas and to exchange criticism. They thus appear to have  
21 created a “market place for ideas” that was intensely robust and that gener-  
22 ated very significant innovation. In both cases, the vast majority of publicly  
23 funded research was conducted through extramural performers, something  
24 that may also have contributed to the formation of effective links between  
25 research and practice. In general, the histories described in this volume high-  
26 light the fact that in each of these sectors, academic interaction with industry  
27 has been a two-way street—one in which important knowledge, expertise,  
28 people, and access to facilities have flowed in both directions.

29 Third, each of our authors stresses the important role that well-designed  
30 institutional mechanisms have played in effectively diffusing the results of  
31 federally funded work. In semiconductors and computers, for example, the  
32 federal government ensured the effective transfer of knowledge by requiring  
33 grant recipients to conduct seminars and distribute publications that actively  
34 disseminated information to others in the field. When AT&T developed  
35 the transistor, the military services that supported the company’s transistor  
36 research also encouraged the dissemination of transistor technology. The  
37 proceedings of symposia funded by the military and held by Bell Labs (the  
38 research arm of AT&T) in the 1950s were widely distributed, and one pro-  
39 duced two thick volumes on semiconductor technology that became known  
40 as “the Bible.”

41 Greenstein’s history of the Internet similarly provides a description of  
42 how DARPA’s insistence that new technologies be embodied in prototypes  
43 and widely shared with other researchers led to the development of a power-  
44

1 ful selection environment that mimicked the role of the market. Problems  
2 were quickly identified, and technologies that were found to be useful were  
3 immediately incorporated into other innovations, triggering a virtuous cycle  
4 of innovation that spread useful ideas rapidly around the research com-  
5 munity.

6 Shih and Wright stress the critical role that the combination of SAESs  
7 and the federally funded agricultural extension service played in developing  
8 locally appropriate technologies and in ensuring their widespread diffusion.  
9 The authors explore the ways in which this structure balanced federal and  
10 state roles by combining federal financial support with state management of  
11 administration and direction of research. Shih and Wright suggest that the  
12 resulting structure provided an avenue to address local research needs while  
13 also exploiting interstate competition to motivate fruitful research.

14 The life sciences industry is also characterized by a particularly vibrant  
15 interchange between the public and private sectors. In their extensive dis-  
16 cussion of the history and institutions that support this lively interface,  
17 Cockburn, Stern, and Zausner stress that the life sciences innovation net-  
18 work is highly decentralized and involves multiple linkages between and  
19 among different institutions, including universities, start-up firms, estab-  
20 lished biotechnology companies, pharmaceutical firms, government, and  
21 venture capitalists. The authors identify a number of factors as particularly  
22 important to maintaining this network. For example, they credit the com-  
23 bination of the Bayh-Dole Act, which allowed federally funded researchers  
24 to take title to their inventions and the *Diamond v Chakrabarty* decision,  
25 which established that genetically engineered organisms were eligible for  
26 patent protection, as instrumental in laying the foundations for the dynamic  
27 early-stage commercialization.

28 They also suggest that the creation of academic medical centers, which  
29 colocate publicly funded researchers working on fundamental problems  
30 with doctors who are actively treating patients, was a particularly impor-  
31 tant institutional invention. Although this structure was initially regarded  
32 with some suspicion, it has proved to be very fruitful—the authors suggest  
33 that it has led to numerous Nobel prizes and has led to numerous findings  
34 that were both fundamental scientific discoveries and also the basis for new  
35 commercially oriented technologies.

36 Several chapters in this volume explore the efficacy of public/private part-  
37 nerships as mechanisms to ensure that publicly funded research is widely  
38 diffused. Here, no single lesson emerges. Arora and Gambardella, for ex-  
39 ample, explore the history of the synthetic rubber program in World War II.  
40 They suggest that the program met two of its initial objectives: it succeeded  
41 in greatly expanding the scale of synthetic rubber production and in improv-  
42 ing synthetic rubber quality, and it attracted many new firms to the industry.  
43 It did not, however, make much progress toward its third goal, the gen-  
44

1 eration and diffusion of significant new knowledge about polymers. Arora  
2 and Gambardella suggest that this may have been because the government  
3 insisted that participating firms adhere to a common recipe—thus slow-  
4 ing down the rate of innovation and leading the many research programs  
5 within the participating firms to be kept rigorously distinct from the publicly  
6 funded efforts.

7 In the case of agriculture, in contrast, Shih and Wright describe a num-  
8 ber of cases in which public/private partnerships appear to have played an  
9 extremely positive role in both stimulating and diffusing critical knowledge.  
10 They note, for example, that research consortium models such as those  
11 adopted by the Latin American Maize Project (LAMP) and the Germplasm  
12 Enhancement of Maize Project (GEM) have been lauded for productively  
13 balancing public goods research with commercial viability. They also note,  
14 however, that while the U.S. Department of Agriculture has formed at least  
15 700 cooperative research and development agreements with private firms,  
16 and while these have produced and commercialized some important inno-  
17 vations, researchers continue to be concerned that these arrangements will  
18 divert funds away from more basic research toward more applied work.

19 Last but not least, the research presented here shows that public funding  
20 of research can also play a critically important role in training the scientific  
21 and technical personnel who become the backbone of an innovative private  
22 sector.

23 Cockburn, Stern, and Zausner, for example, suggest that this dynamic  
24 has been fundamental to the development of the extraordinarily innova-  
25 tive private sector that characterizes the life sciences. They note, for ex-  
26 ample, that the practice of funding public research through peer-reviewed  
27 extramural NIH funding has created a high level of competition for funds  
28 and has supported the development of departments in universities focused  
29 on the biosciences. Within these departments, grant-supported training of  
30 PhD and postdoctoral students engaging in frontier research has helped to  
31 create a mobile, knowledge-based workforce that has moved fluidly between  
32 industry and academia. Between the early 1970s and today, the number of  
33 life science doctorate holders employed in academia more than doubled, and  
34 there has also been a significant expansion in the number of bachelor's-level  
35 students who receive a degree in the life sciences fields. Universities have  
36 played a similarly critical role in the chemical industry by institutionalizing  
37 the learning being created by firms and by training students. Arora and  
38 Gambardella credit universities for creating the disciplines of petroleum  
39 engineering, chemical engineering, polymer chemistry, and polymer engi-  
40 neering.

41 Mowery makes the point that federal support of fundamental R&D  
42 in semiconductors and computers played an instrumental role in build-  
43 ing the “R&D infrastructure”—the institutions that identified and trained  
44

1 the highly skilled people whose work was fundamental to innovation in the  
2 commercial sector. For example, in the case of the software industry, the  
3 Semi-Automatic Ground Environment (SAGE) air defense project acted as  
4 a “university” of sorts for hundreds of software programmers—a develop-  
5 ment that laid the foundation for the future development of the industry  
6 within the United States. Similarly, the (much later) development of the so-  
7 called shrink-wrapped or mass market software industry was greatly aided  
8 by a (largely federally funded) university-based research complex. Green-  
9 stein makes an analogous point in the case of the Internet, suggesting that  
10 many of the key players who went on to private-sector careers developed  
11 their expertise in the context of early government-funded work.

12 Taken together, the work presented here is, thus, broadly consistent with  
13 much of the current energy innovation policy literature: in the highly inno-  
14 vative industries reviewed here, public funding for fundamental research  
15 was not only significant and sustained but also managed in such a way that  
16 it was tightly linked to practice, widely diffused, and led to the generation  
17 of a highly trained private-sector workforce. The ways in which this was  
18 accomplished, however, differ significantly across each industry, with each  
19 history highlighting governance mechanisms that may be worth considering  
20 in the energy context.

## 21 Demand and Induced Innovation

22  
23 Rapidly growing demand plays two key roles in stimulating innovation.  
24 First and foremost, it signals a plausibly large and potentially rapidly grow-  
25 ing market—something that greatly accelerates private-sector investment  
26 in innovation and the rapid diffusion of new technologies. Second, and per-  
27 haps more subtly, growing demand provides an important opportunity for  
28 immediate feedback from the market, whereby new product development  
29 underpins innovation that is more directly responsive to real market needs  
30 and less likely to fall prey to the isolation of the ivory tower.

31 In every one of the sectors explored here, rapidly growing demand trig-  
32 gered both extensive private-sector investment and extensive diffusion of  
33 new technology. For example, Cockburn, Stern, and Zausner’s review of  
34 innovation in the life sciences suggests that one of the reasons R&D invest-  
35 ment rates in the biopharmaceutical industry have remained so consis-  
36 tently high is because private firms have been consistently assured of robust  
37 demand for innovative products as historically, so many health care needs  
38 have remained unmet. The authors note that the nature of demand for bio-  
39 pharmaceuticals has profoundly affected the life sciences innovation system.  
40 Intrinsically high willingness to pay for products that extend life or improve  
41 the quality of life—especially in the notably price-insensitive U.S. health  
42 care delivery system—has translated into relatively price-inelastic and stable  
43 demand. As a result, firms have been able to secure significant returns over  
44

1 a long period of time by focusing on the development and commercial-  
2 ization of innovative and novel biotherapeutic compounds. In agriculture,  
3 Shih and Wright find that similarly unmet needs—for higher yields and  
4 improved crop varieties able to withstand extreme weather, weed encroach-  
5 ment, and constantly evolving pests—have acted as a strong stimulus to  
6 innovation.

7 In both the semiconductor and computer industries, the large-scale entry  
8 of private firms coincided with a decline in prices, partly as a result of early  
9 government purchases, and an explosion in demand as both technologies  
10 allowed customers to do things that had never been done before. Similarly,  
11 the early commercialization of the Internet—and the excitement about its  
12 potential uses—was associated with a rush of private firms into the indus-  
13 try and a dramatic increase in the pace of innovation. Arora and Gam-  
14 bardella, in their chapter on the chemical industry, suggest that the explosion  
15 in demand for chemicals that accompanied the rapid industrialization of  
16 the early twentieth century was a critical factor in persuading private firms  
17 to invest heavily in chemical research. They also note that a lack of com-  
18 mercial demand was almost certainly the most important factor leading to  
19 the perceived failure of the government’s Synfuels programs.

20 As many scholars have noted, one of the major barriers to the replication  
21 of these kinds of dynamics in the energy industry is the fact that “low-  
22 carbon” or “carbon-free” energy is typically indistinguishable from “dirty”  
23 energy at the point of consumption. In the industries whose history we  
24 include here—agriculture, chemicals, semiconductors, computers, the Inter-  
25 net, and biopharmaceuticals—once the technology reached some critical  
26 threshold of performance, demand exploded because the new technologies  
27 offered dramatic improvements over existing products, in many cases meet-  
28 ing consumer needs that had never been met before. This is unlikely to be  
29 the case with energy innovation.

30 Many authors working within the energy innovation policy literature  
31 have, therefore, argued that the single most important thing public policy  
32 can do to support the accelerated development and deployment of clean  
33 energy technologies is to create demand for low-carbon energy (Aghion  
34 et al. 2009; Anadon and Holdren 2009; Anadon, Gallagher, and Bunn 2009;  
35 Newell 2008, 2010; Stavins 2008; Weiss and Bonvillian 2009). Attention has  
36 focused on two kinds of mechanisms: on the creation of a “price” for carbon  
37 through some kind of tax or cap and trade regime or on the direct creation of  
38 markets through, for example, the imposition of renewable energy standards  
39 in energy purchasing or through the direct government support of first-in-  
40 class technology implementation through subsidy or purchase.

41 Proponents of the first approach stress its likely economic and technical  
42 efficiency (Stavins 2008; Newell 2010; Aghion et al. 2009). For example,  
43 Mowery, Nelson, and Martin (2009) suggest that a “Manhattan” or “Apollo”  
44 project approach is not an appropriate model for clean energy innovation.

1 In the defense and space industries, the government can entirely define the  
2 nature of customer demand because *it* is the final customer. In the case of  
3 clean energy, however, Mowery Nelson, and Martin argue that it is deeply  
4 implausible to think that any discrete government program could foresee the  
5 precise technological solutions that will be appropriate. This is particularly  
6 true given that these technologies will need to be deployed throughout the  
7 world by many different actors, the deployment decisions will require huge  
8 outlays of private funds, and their largely embryonic state means that they  
9 will continue to evolve and improve over many years.

10 Proponents of the second approach, in contrast, stress the need for public  
11 subsidies to cross the “valley of death” between technological proof of con-  
12 cept and first commercialization, suggesting that this valley is likely to be  
13 particularly wide and expensive in the case of energy (Lester 2009; Ogden,  
14 Podesta, and Deutch 2008).

15 The results presented in the following are consistent with both perspec-  
16 tives. On the one hand, there are several cases in which the federal govern-  
17 ment acted as the “first customer” for a new technology, arguably providing  
18 the critical support that was required to bridge the gap between prototype  
19 and private commercialization. Mowery’s account of the early development  
20 of the semiconductor industry is an intriguing example of this dynamic in  
21 action. He documents how the prospect of large military procurement con-  
22 tracts in the early years of the semiconductor industry acted as a “prize,”  
23 stimulating widespread entry and extensive innovation. He also details the  
24 important role that early military demand played in driving up industry  
25 production volumes and driving down production costs to the point where  
26 the new technology became commercially viable. He contrasts the success  
27 of these early efforts with the much more mixed track record of the Very  
28 High Speed Integrated Circuit (VHSIC) program—an early 1980s program  
29 that failed to meet its objectives and failed to successfully compete with the  
30 U.S. semiconductor market, which by then was dominated by commercial  
31 applications.

32 Mowery also documents the central role that federal procurement played  
33 in the early days of the computer industry. The first electronic U.S. digi-  
34 tal computer was purchased by the military, and the first fully operational  
35 stored program computer built in the United States was purchased by the  
36 National Bureau of Standards. Even in the case of IBM’s 650—the most  
37 commercially successful machine built in the 1950s—the projected sales of  
38 fifty machines to the federal government was critical to IBM’s decision to  
39 move the computer to full-scale commercial development. In the 1970s and  
40 1980s, the government’s role as purchaser of high-performance computer  
41 equipment remained significant. Mowery further argues that federal pro-  
42 curement fostered the early development of the software industry. The rapid  
43 growth of the industry between 1969 and 1980 that gave the U.S. industry  
44 a worldwide advantage was spurred by federal willingness to invest in large,

1 complex software development projects at a time when the commercial mar-  
2 ket for such projects did not exist.

3 Early government demand also looms large in Greenstein’s account of  
4 how the DARPA-funded research that proved ultimately to be immensely  
5 useful despite the absence of immediate commercial demand. Greenstein  
6 makes the point that DARPA’s investments in the development of large-  
7 scale packet switching and a “networks of networks” were considered highly  
8 risky and that no one foresaw any commercial application for them. This is  
9 not to say, however, that the early research went forward without any interac-  
10 tion with potential customers or without some sense of what demand might  
11 look like. Rather, the military had identified potential military uses for some  
12 of the new technology, and this potential military application shaped the  
13 early DARPA research.

14 Similarly, while it is the case that in none of the industries whose history is  
15 outlined in the following did the government explicitly set a price for the new  
16 technology, Cockburn, Stern, and Zausner suggest that in the case of the  
17 life sciences, the government has played a critical role in sustaining demand  
18 for innovative biopharmaceuticals. They hypothesize that—“whether by  
19 accident or design”—the interaction between the patent system, the Food  
20 and Drug Administration (FDA) regulatory process, and the way care is  
21 paid for within the U.S. health care system provide strong incentives for  
22 breakthrough innovation. The combination of a high willingness to pay  
23 for products, insurance that insulates purchasers from paying the marginal  
24 price, and the Hatch-Waxman regulatory framework provide strong incen-  
25 tives for the private sector to develop blockbuster therapies. These factors  
26 also provide incentives to develop a stream of innovations over time as the  
27 threat of generic entry upon patent expiration means that the returns to any  
28 single innovation are transitory.

29 What are the implications of these histories for our understanding of the  
30 role of government in creating demand for low-carbon energy? The indus-  
31 tries we explore here differ crucially from energy in that one of the most  
32 important outcomes of innovation in each of them has been the creation  
33 of highly differentiated products that have met hitherto unmet needs, while  
34 “clean” energy cannot be easily differentiated at the point of delivery. It is  
35 thus difficult to imagine creating demand for low-carbon energy without  
36 government intervention—in the form of a price for GHG emissions, pur-  
37 chase mandates, or subsidies. Much ink has been spilled on the question of  
38 which of these interventions is likely to be the most economically efficient  
39 (see, for example, Popp, Newell, and Jaffe 2010; Jaffe, Newell, and Stavins  
40 2005). The histories contained in this volume do not attempt to resolve this  
41 debate, but they do suggest that each may be effective, and they underscore  
42 the imperative of inducing clean energy demand if we are to see substan-  
43 tial, sustained, private-sector investment in energy innovation and the rapid  
44 deployment of new technologies.

1  
2 Enabling Competition: Antitrust, Intellectual  
3 Property, and Standards Policy

4 Accelerating innovation requires increasing both the supply of and the  
5 demand for new technologies. Beyond supply and demand, however, the  
6 theme that emerges most clearly from our histories is the important role that  
7 public policy has played in fostering vigorous competition and “markets  
8 for technology” in each industry and the centrally important role that this  
9 competition has played in accelerating innovation. Here again, our histo-  
10 ries suggest that there is no single policy or set of policies that is always  
11 appropriate but that policy design must be actively tailored to the structure  
12 of the industry and the particular circumstances of the market. They focus  
13 attention on three policy instruments in particular: antitrust, intellectual  
14 property, and support for public open standards.

15 In the case of chemicals, Arora and Gambardella explore in some depth  
16 the role that appropriately narrowly defined patents and aggressive antitrust  
17 enforcement have played in encouraging entry in general and the rise of  
18 specialized engineering firms in particular. They note that new technologies  
19 in the industry have typically diffused extraordinarily fast, largely because  
20 of the presence of a robust market for technology fueled by the activities of  
21 small, independent specialized engineering firms. These firms not only build  
22 about 75 percent of all new plants, allowing easier entry into the industry,  
23 but are also responsible for about 35 percent of all new process inventions.  
24 Arora and Gambardella suggest that the existence of this market reflects the  
25 fact that patents in chemicals are both precise and narrowly specified. This  
26 makes the patents effective in protecting particular innovations and also  
27 allows competitors to enter the industry in closely related areas.

28 Arora and Gambardella also suggest that antitrust action has accelerated  
29 the widespread industry practice of licensing, focusing particularly on the  
30 cases of Standard Oil and DuPont. In 1909 to 1910, Standard Oil scientist  
31 William Burton developed the first commercially successful cracking pro-  
32 cess. It was a major innovation in refining technology, but Standard Oil was  
33 reluctant to invest in the process. However, as a result of an antitrust suit,  
34 the original Standard Oil was broken up into several firms in 1911, among  
35 which was Standard Oil of Indiana, where Burton worked. Standard Oil of  
36 Indiana not only commercialized Burton’s process, but also licensed it to a  
37 number of other oil refiners. Similarly, DuPont was split into three separate  
38 firms following a successful antitrust suit in 1913 that also helped to convince  
39 DuPont’s managers that the only path to future growth lay in entering new  
40 markets through innovation, rather than through the acquisition of existing  
41 producers.

42 In the life sciences, Cockburn, Stern, and Zausner note that there are mul-  
43 tiple routes to the highly diversified, highly innovative private-sector “eco-  
44 system” that characterizes the industry. The fact that this is one of the very

1 few industries in which patent rights can be crisply defined appears to play an  
2 important role—notably by undergirding a vigorous biotechnology sector  
3 whose numerous small firms are largely venture capital funded. They note  
4 that the industry has seen the founding of more than 1,300 biotechnology  
5 companies in the United States and approximately 5,000 worldwide and that  
6 by the early 2000s, 25 to 40 percent of all pharmaceutical sales came from  
7 products having their origins in biotechnology. There has also been signifi-  
8 cant entry of specialized suppliers of biomedical materials and tools (e.g.,  
9 gene sequencers and biomaterials); the development of contract research  
10 organizations that can provide expertise in areas such as early-stage clinical  
11 trials and the development of specialized managers, lawyers, and venture  
12 capitalists, who together can facilitate more effective transactions in what  
13 has become an increasingly complex web of relationships between academe,  
14 entrepreneurs, and downstream firms. Their analysis parallels Arora and  
15 Gambardella’s suggestion that the emergence of a well-functioning “market  
16 for technology” can be hugely valuable in both stimulating private-sector  
17 innovation and in supporting its widespread diffusion. They stress the fact  
18 that both the structure of demand and the nature of regulation has meant  
19 that competition in the industry has been largely focused around inno-  
20 vation.

21 Greenstein’s chapter describing the history of the Internet is one of the  
22 most eloquent on this set of issues. He suggests that effective competition  
23 was critical to the development of the Internet and rested on three key factors:  
24 “economic experiments, vigorous standards competition, and entrepre-  
25 neurial invention.” He stresses the crucial role that federal policy played in  
26 supporting all three factors. On the one hand, many of the established firms  
27 in the industry—including AT&T, the “Baby Bells,” and IBM—actively  
28 rejected the possibility of investment in commercializing services related to  
29 Transmission Control Protocol/Internet Protocol (TCP/IP; the technologi-  
30 cal “core” of what later became the Internet) in the late 1980s. On the other  
31 hand, long-standing regulation of the telecommunications industry that  
32 favored new entry meant that the commercialization of the Internet was  
33 accompanied by a dramatic wave of new firm foundation.

34 Greenstein’s account also explores the ways in which the process of stan-  
35 dard setting in the industry was instrumental in supporting widespread,  
36 highly distributed innovation. Many of the key patents in the industry were  
37 publicly owned. This public ownership, coupled with the fact that early con-  
38 trol of the technology rested largely in the hands of public-sector research-  
39 ers, built a set of processes for standard setting that has been transparent  
40 and highly participatory. Greenstein makes the point that while this process  
41 has sometimes been frustrating, it has enabled the development of a highly  
42 complex value chain in which private, proprietary “platforms” coexist with  
43 public technologies in a way that makes it possible for small, innovative firms  
44 to innovate successfully without having to reinvent the entire system.

1 Mowery notes the importance to the semiconductor industry of both  
2 AT&T's ongoing antitrust litigation and of the government's procurement  
3 policies. Both encouraged the widespread diffusion of semiconductor tech-  
4 nology and subsequent rapid entry into the industry. In the early 1950s,  
5 AT&T was reluctant, for antitrust reasons, to expand beyond its core base  
6 of telecommunications, thus leaving sales of the new technology into other  
7 applications as a tempting market for new entrants. At the same time, fed-  
8 eral policies—driven partly by the desire to have “second sources” available  
9 for key military components—encouraged widespread diffusion of the new  
10 knowledge. For example, Mowery describes a symposium held at Bell Labs  
11 in 1951 attended by 130 industrial representatives, 121 military personnel,  
12 and 41 university scientists whose proceedings were widely distributed at  
13 government expense. The military was also willing to award large procure-  
14 ment contracts to newly founded firms, another mechanism that Mowery  
15 suggests was instrumental to the development of a highly competitive,  
16 highly innovative market structure that he contrasts with the very different  
17 semiconductor industries that emerged in Germany and Japan.

18 Mowery describes a similar dynamic in the case of computers—docu-  
19 menting how the military's belief that a strong technical infrastructure in  
20 support of innovation could only be built by the widest possible dissemina-  
21 tion of technology—which led them to both use federal procurement poli-  
22 cies to support new firms and to invest aggressively in information diffusion.  
23 He also describes how the IBM antitrust suit and subsequent consent decree  
24 was almost certainly instrumental in encouraging widespread entry into the  
25 hardware industry and the entry of many independent software vendors. He  
26 further observes that many of these entrants had been suppliers of com-  
27 puter services to federal government agencies. He speculates that U.S. import  
28 policies—which were notably more liberal than those adopted by Western  
29 European and Japanese governments—also played an important role in  
30 stimulating the competitiveness of the IT industry and the rapid declines  
31 in price-performance ratios that so accelerated the adoption of IT and the  
32 subsequent U.S. dominance of the industry.

33 In agriculture, in contrast, Shih and Wright voice deep concern over the  
34 role that patents play in the industry. They note the increasing evidence  
35 that multiple, mutually blocking intellectual property claims on inputs are  
36 hindering access to research tools that can be incorporated in the marketed  
37 products of agricultural research (Wright and Pardey 2006; Pardey et al.  
38 2007). The authors suggest that the increasing concentration of the indus-  
39 try—for example, one estimate suggests that the top ten firms own more  
40 than half of all the agricultural biotech patents granted through 2000—is  
41 plausibly an attempt to retain “freedom to operate” by the major players  
42 and suggest that it may retard innovation in the industry. Even more criti-  
43 cally, they suggest that the rising application of intellectual property rights  
44 to plant components and processes imposes high transaction costs for

1 researchers who must acquire or license fragmented proprietary inputs to  
2 develop and commercialize a single downstream innovation. They further  
3 suggest that patents on locked-in but otherwise noncrucial genetic technol-  
4 ogies have been retarding innovation and affecting the market structure of  
5 private research.

6 Although some energy policy analysts have explored the role of intellectual  
7 property regimes in shaping energy innovation (Reichman et al. 2008; Popp,  
8 Newell, and Jaffe 2010; Sagar and Anadon 2009), this has not been an area  
9 of central concern to scholars working in the field. Perhaps this approach  
10 reflects the belief that the scale of energy investment is such that only large  
11 established firms can be expected to introduce major innovations—but the  
12 importance of new entry to recent progress in both wind and solar technol-  
13 ogies at least raises the question of whether some of the instruments that  
14 appear to have been important in the industries we study might also play an  
15 important role in stimulating vigorous, innovation-focused competition in  
16 the energy industry.

## 17 18 **Conclusions**

19  
20 At the broadest level, the histories presented here are very much consistent  
21 with widely held views within the energy innovation policy literature. In  
22 general, this literature has suggested that greatly increasing rates of energy  
23 innovation requires creating significant demand for low-carbon technol-  
24 ogies; substantially increased federal funding for well-managed research;  
25 and, in at least some cases, support for the initial deployment of new tech-  
26 nologies. As the other markets explored in this volume do not face the same  
27 degree of unpriced environmental externality, there is no straightforward  
28 equivalent to a carbon price in the history of agriculture, chemicals, IT, or  
29 biopharmaceuticals. Nonetheless, our authors outline a number of ways in  
30 which public policy has often stimulated demand, particularly in the early  
31 stages of a technology's evolution, and confirm that the expectation of rap-  
32 idly growing demand appears to have been a major stimulus to private-  
33 sector investment in innovation. Each history also confirms the centrality of  
34 publicly funded research to the generation of innovation, particularly in the  
35 early stages of an industry's history, and highlights a range of institutional  
36 mechanisms that have enabled it to be simultaneously pathbreaking and  
37 directly connected to industrial practice.

38 Our histories depart somewhat from the bulk of the energy innovation  
39 policy literature in focusing attention on the role of vigorous competition—  
40 particularly entry—in stimulating innovation, suggesting that in several  
41 industries, a mix of public policies—including procurement, antitrust, and  
42 intellectual property protection—played an important role in stimulating  
43 innovation by encouraging extensive competition and entry by newly founded  
44 firms. Many of the most innovative industries profiled here have been char-

acterized by a lively “innovation ecosystem” that both rapidly incorporates the results of publicly funded research and supports widespread private-sector experimentation and rapid entry. There are, of course, important differences between the industries profiled here and the energy sector, but we believe that exploring the potential of these kinds of innovation ecosystems in clean energy might be a fruitful avenue for future research.
